- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient is regularly using these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Dietary recommendations may be indicated and will vary depending on the type and severity of the condition. Elimination of alcohol ingestion, and a diet optimized for convalescence are commonly included in the treatment plan. A high-calorie, high-protein, moderate-fat diet with a high fluid intake is often recommended for patients with hepatitis.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- *Cultural and social considerations:*

Recognize anxiety related to test results, and and be supportive of impaired activity related to lack of neuromuscular control, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Counsel the patient, as appropriate, regarding the risk of transmission and proper prophylaxis. Hepatitis B immune globulin (HBIG) vaccination should be given immediately after situations in which there is a potential for HBV exposure (e.g., accidental needle stick, perinatal period, sexual contact) for temporary, passive protection.

- Counsel the patient and significant contacts, as appropriate, that HBIG immunization is available and has in fact become a requirement in many places as part of childhood immunization and employee health programs. Parents may choose to sign a waiver preventing their newborns from receiving the vaccine; they may choose not to vaccinate on the basis of philosophical, religious, or medical reasons. Vaccination regulations vary from state to state.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include alanine aminotransferase, alkaline phosphatase, aspartate aminotransferase, bilirubin, culture anal and chlamydia group antibody, γ-glutamyltranspeptidase, hepatitis B and C antibodies/antigens human immunodeficiency virus serology, liver biopsy, and syphilis serology.

HEPATOBILIARY SCAN

SYNONYM/ACRONYM: Hepatobiliary imaging, biliary tract radionuclide scan, hepatobiliary scintigraphy, gallbladder scan, cholescintigraphy, HIDA (a technetium-99m disopropyl analogue) scan.

AREA OF APPLICATION: Bile ducts.

CONTRAST: Intravenous contrast medium (aminodiacetic acid compounds), usually combined with technetium-99m.

DESCRIPTION & RATIONALE: The hepatobiliary scan is a nuclear medicine study of the hepatobiliary excretion system. It is primarily used to determine the patency of the cystic and common bile ducts, but it can also be used to determine overall hepatic function, gallbladder function, presence of gallstones (indirectly), and sphincter of Oddi dysfunction. Technetium (Tc-99m) HIDA (tribromoethyl, an aminodiacetic acid) is injected intravenously (IV) and excreted into the bile duct system. A gamma camera detects the radiation emitted from the injected contrast medium, and a representative image of the duct system is obtained. The results are correlated with other diagnostic studies, such as IV cholangiography, computed tomography (CT) scan of the gallbladder, and ultrasonography. Gallbladder emptying or ejection fraction can be determined by administering a fatty meal or cholecystokinin to the patient. This procedure can be used before and after surgery to determine the extent of bile reflux. ■

INDICATIONS:

- Aid in the diagnosis of acute and chronic cholecystitis
- Aid in the diagnosis of suspected gallbladder disorders, such as inflammation, perforation, or calculi
- Assess enterogastric reflux
- Assess obstructive jaundice when done in combination with radiography or ultrasonography
- Determine common duct obstruction caused by tumors or choledocholithiasis
- Evaluate biliary enteric bypass patency
- Postoperatively evaluate gastric surgical procedures and abdominal trauma

RESULT

Normal Findings:

- Normal shape, size, and function of the gallbladder with patent cystic and common bile ducts

Abnormal Findings:

- Acalculous cholecystitis
- Acute cholecystitis
- Chronic cholecystitis
- Common bile duct obstruction secondary to gallstones, tumor, or stricture
- Congenital biliary atresia or choledochal cyst
- Postoperative biliary leak, fistula, or obstruction
- Trauma-induced bile leak or cyst

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment

- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Bilirubin levels greater than or equal to 30 mg/dL, depending on the radionuclide used, which may decrease hepatic uptake
- Other nuclear scans done within the previous 24 to 48 hours
- Fasting for more than 24 hours before the procedure, total parenteral nutrition, and alcoholism
- Ingestion of food or liquids within 2 to 4 hours before the scan

Other considerations:

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue can produce erroneous hot spots.
- Inaccurate timing of imaging after the radionuclide injection can affect the results.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiologic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure detects inflammation or obstruction of the gallbladder or bile duct system.
- Obtain a history of the patient's complaints and symptoms, including a list of known allergens.
- Obtain a history of results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Hepatobiliary System table.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient's current medications.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Explain the purpose of the test and how the procedure is performed. Inform the patient that the procedure is performed in a nuclear medicine department, usually by a technologist and support staff, and usually takes approximately 60 to 90 minutes. Inform the patient that the technologist will place him or her in a supine position on a flat table for the injection of contrast medium. Delayed images are needed up to 24 hours after the initial injection. The patient may leave the department and return later to undergo delayed imaging.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psy-

chological support before, during, and after the procedure.

- Restrict food and fluids for 4 to 6 hours before the scan.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that the patient fasted for 4 to 6 hours before the scan, unless otherwise indicated.
- Ask patient to remove jewelry, including watches, and any other metallic objects.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to lie still during the procedure because movement produces unclear images.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in a supine position on a flat table with foam wedges to help maintain position and immobilization.
- IV radionuclide is administered, and the upper-right quadrant of the abdomen is scanned immediately, with images then taken every 5 minutes for the first 30 minutes and every 10 minutes for the next 30 minutes. Delayed views are taken in 2, 4, and 24 hours if the gallbladder cannot be visualized, in order to differentiate acute from chronic cholecystitis or to detect the degree of obstruction.
- IV morphine may be administered during the study to initiate spasms of the sphincter of Oddi, forcing the radionuclide into the gallbladder, if the organ is not visualized within 1 hour of injection of the radionuclide. Imaging is then done 20 to 50 minutes later to determine delayed visualization or nonvisualization of the gallbladder.
- If gallbladder function or bile reflux is being assessed, the patient will be given a fatty meal or cholecystokinin 60 minutes after the injection.
- Wear gloves during the radionuclide administration and while handling the patient's urine.
- The results are recorded on film or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, medications, and activity, after imaging is complete, as directed by the health care practitioner.
- Advise patient to drink increased amounts of fluids for 24 to 48 hours to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hours.
- Inform the patient to immediately flush the toilet after each voiding after the procedure, and to meticulously wash hands with soap and water after each voiding for 24 hours after the procedure.
- Tell all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash ungloved hands after the gloves are removed.
- Instruct the patient in the care and assessment of the injection site. Observe for bleeding, hematoma formation, and inflammation.
- A written report of the examination will be completed by a health care practitioner specializing in this

branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.

- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the abdomen, magnetic resonance imaging of the abdomen, and ultrasound of the liver and bile ducts.

HER-2/NEU ONCOPROTEIN

SYNONYM/ACRONYM: c-erb-B2.

SPECIMEN: Breast tissue or cells.

REFERENCE VALUE: (Method: Immunocytochemical) Negative.

DESCRIPTION & RATIONALE: Breast cancer is the most common newly diagnosed cancer in American women. It is the second leading cause of cancer-related death. The presence of abnormal amounts of a protein called human epidermal growth factor receptor 2 (HER-2/neu oncoprotein) is helpful in establishing histologic evidence of metastatic breast cancer. Overexpression of this protein results from an acquired genetic mutation and occurs in 25% to 30% of patients with metastatic breast cancer. Metastatic breast cancer patients with high levels of HER-2/neu oncoprotein have a poor prognosis: They have rapid tumor progression, increased rate of recurrence, poor response to standard therapies, and a lower survival rate.

The specimen is collected by fine-needle or open biopsy. The tissue sample is treated with a material that binds to HER-2/neu oncoprotein. A dye is added to the tissue sample; areas of tissue that have large amounts of HER-2/neu oncoprotein are indicated by high-intensity color on the tissue sample. ■

INDICATIONS: Evidence of breast lesion by palpation, mammography, or ultrasound

RESULT

Positive findings in: Breast cancer

CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to assist in the prognosis and in the management of response to therapy for breast cancer.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune and reproductive systems and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Reproductive System tables.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, acetylsalicylic acid, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation. It is recommended that use be discontinued 14 days before dental or surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that it may be necessary to shave the site before the procedure. Instruct that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain related to the procedure. Explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the percutaneous biopsy; a general anesthesia will be administered prior to the open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used, but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by a health care practitioner specializing in this procedure. The surgical procedure usually takes about 20 to 30 minutes to complete, and that sutures may be necessary to close the site. A needle biopsy usually takes about 15 minutes to complete.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during and after the procedure.
- Explain that an intravenous (IV) line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- Ensure that anticoagulant therapy has been withheld for the appropriate amount of days prior to the procedure. Amount of days to withhold medication is dependant on the type of anticoagulant. Notify health care practitioner if patient anticoagulant therapy has not been withheld.

Open biopsy:

- Instruct the patient that nothing should be taken by mouth for 6 to 8 hours prior to a general anesthetic.

Needle biopsy:

- Instruct the patient that nothing should be taken by mouth for at least 4 hours prior to the procedure

to reduce the risk of nausea and vomiting.

General:

- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 4 to 8 hours prior to the procedure, depending on the anesthetic chosen for the procedure.
- Have emergency equipment readily available.
- Have the patient void before the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location, especially left or right breast.
- Assist the patient to the desired position depending on the test site to be used, and direct the patient to breath normally during the beginning of the general anesthesia. Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- Record baseline vital signs and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
- After the administration of general or local anesthesia, cleanse the site with an antiseptic solution, and drape the area with sterile towels.

Open biopsy:

- After administration of general anesthesia and surgical prep is completed, an incision is made, suspicious area(s) are located, and tissue samples are collected.

Needle biopsy:

- Direct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes. Instruct the patient to take a deep breath, exhale forcefully, and hold the breath while the biopsy needle is inserted and rotated to obtain a core of breast tissue. Once the needle is removed, the patient may breathe. Pressure is applied to the site for 3 to 5 minutes, then a sterile pressure dressing is applied.

General:

- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- Apply a sterile dressing to the site.
- Place tissue samples in properly labeled specimen container containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume preoperative diet, as directed by the health care practitioner.
- Monitor vital signs every 15 minutes for 1 hour, and then every 2 hours for 4 hours, and then as ordered by the health care practitioner. Monitor temperature every 4 hours for 24 hours. Compare with baseline values. Notify the health care practitioner if temperature is elevated. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

- Observe the biopsy site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the site. Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to immediately report chills or fever. Instruct the patient to keep the site clean and change the dressing as needed.
- Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the health care practitioner.
- Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle Provide teaching and information regarding the clinical implications of the test results, as appropriate. Inform the patient about hormone therapy, as appropriate based on test results. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Inform the patient of a follow-up appointment for removal of sutures, if indicated. Instruct and educate the patient on how to perform monthly breast self-examination and emphasize, as appropriate, the importance of having a mammogram performed annually. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include breast biopsy, CA 15-3, carcinoembryonic antigen, and estrogen and progesterone receptors.

HEXOSAMINIDASE A AND B

SYNONYM/ACRONYM: N/A.

SPECIMEN: Serum (3 mL) collected in a red-top tube. After the specimen is collected, it *must* be brought immediately to the laboratory. The specimen must be allowed to clot for 1 to 1.5 hours in the refrigerator. The serum should be removed and frozen immediately.

REFERENCE VALUE: (Method: Fluorometry)

Total Hexosaminidase	Conventional Units	SI Units (Conventional Units × 0.0167)
Noncarrier	589–955 nmol/h/mL	9.83–15.95 U/L
Heterozygote	465–675 nmol/h/mL	3.30–5.39 U/L
Tay-Sachs homozygote	Greater than 1027 nmol/h/mL	Greater than 17.15 U/L

Hexosaminidase A	Conventional Units	SI Units (Conventional Units × 0.0167)
Noncarrier	456–592 nmol/h/mL	7.2–9.88 U/L
Heterozygote	197–323 nmol/h/mL	3.3–5.39 U/L
Tay-Sachs homozygote	0 nmol/h/mL	0 U/L

Hexosaminidase B	Conventional Units	SI Units (Conventional Units × 0.0167)
Noncarrier	12–32 nmol/h/mL	0.2–0.54 U/L
Heterozygote	21–81 nmol/h/mL	0.35–1.35 U/L
Tay-Sachs homozygote	Greater than 305 nmol/h/mL	Greater than 5.09 U/L

DESCRIPTION & RATIONALE: Hexosaminidase is a lysosomal enzyme. There are three predominant isoenzymes: hexosaminidase A, B, and S. Deficiency results in the accumulation of complex sphingolipids and gangliosides in the brain. There are more than 70 lysozymal enzyme disorders. Testing for hexosaminidase A is done to determine the presence of Tay-Sachs disease, a genetic autosomal recessive condition characterized by early and progressive retardation of physical and mental development. This enzyme deficiency is most common among Ashkenazic Jews. Patients who are homozygous for this trait have no hexosaminidase A and have greatly elevated levels of hexosaminidase B; signs and symptoms include red spot in the retina, blindness, and muscular weakness. Tay-Sachs disease results in early death, usually by age 3 or 4 years. ■

INDICATIONS:

- Assist in the diagnosis of Tay-Sachs disease

- Identify carriers with hexosaminidase deficiency

Result

Increased in:

- Total
  Gastric cancer
  Hepatic disease
  Myeloma
  Myocardial infarction
  Pregnancy
  Symptomatic porphyria
  Vascular complications of diabetes
- Hexosaminidase A
  Diabetes
  Pregnancy
- Hexosaminidase B
  Tay-Sachs disease

Decreased in:

- Total
  Sandhoff's disease
- Hexosaminidase A
  Tay-Sachs disease
- Hexosaminidase B
  Sandhoff's disease

Critical values: N/A

Interfering factors: Drugs that may increase hexosaminidase levels include ethanol, isoniazid, oral contraceptives, and rifampin.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to identify carrier status for Tay-Sachs disease.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's reproductive system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Reproductive System table.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.

- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Encourage the family to seek genetic counseling if results are abnormal. It is also important to discuss feelings the mother and father may experience (e.g., guilt, depression, anger) if abnormalities are detected. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the National Tay Sachs and Allied Diseases Association *(http://www.ntsad.org)*.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- A related laboratory test is chromosome analysis.

HOLTER MONITOR

SYNONYMS/ACRONYM: Holter electrocardiography, ambulatory monitoring, ambulatory electrocardiography, event recorder.

AREA OF APPLICATION: Heart.

CONTRAST: None.

DESCRIPTION & RATIONALE: The Holter monitor records electrical cardiac activity on a continuous basis for 24 to 48 hours. This noninvasive study includes the use of a portable device worn around the waist or over the shoulder that records cardiac electrical impulses on a magnetic tape.

The recorder has a clock that allows accurate time markings on the tape. The patient is asked to keep a log or diary of daily activities and to record any occurrence of cardiac symptoms. When the client pushes a button indicating that symptoms (e.g., pain, palpitations, dyspnea, syncope) have occurred, an event marker is placed on the tape for later comparison with the cardiac activity recordings and the daily activity log. Some recorders allow the data to be transferred to the physician's office by telephone, where the tape is interpreted by a computer to detect any significantly abnormal variations in the recorded waveform patterns. ■

INDICATIONS:

- Detect arrhythmias that occur during normal daily activities, and correlate them with symptoms experienced by the patient
- Evaluate activity intolerance related to oxygen supply and demand imbalance
- Evaluate chest pain, dizziness, syncope, and palpitations
- Evaluate the effectiveness of antiarrhythmic medications for dosage adjustment, if needed
- Evaluate pacemaker function
- Monitor for ischemia and arrhythmias after myocardial infarction or cardiac surgery before changing rehabilitation and other therapy regimens

RESULT

Normal Findings:

- Normal sinus rhythm

Abnormal Findings:

- Arrhythmias such as premature ventricular contractions, bradyarrhythmias, tachyarrhythmias, conduction defects, and bradycardia
- Cardiomyopathy
- Hypoxic or ischemic changes
- Mitral valve abnormality
- Palpitations

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair the results of the examination:

- Improper placement of the electrodes or movement of the electrodes
- Failure of the patient to maintain a daily log of symptoms or to push the button to produce a mark on the strip when experiencing a symptom

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure evaluates how the heart responds to normal activity or to a medication regimen.
- Obtain a history of the patient's cardiovascular system, cardiac disease, and present cardiovascular status, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Cardiovascular System table.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about

pain related to the procedure. Explain that no electricity is delivered to the body during this procedure and that no discomfort is experienced during monitoring. Inform the patient that the electrocardiography (ECG) recorder is worn for 24 to 48 hours, at which time the patient is to return to the laboratory with an activity log to have the monitor and strip removed for interpretation.

- Advise the patient to avoid contact with electrical devices that can affect the strip tracings (e.g., shavers, toothbrush, massager, blanket) and to avoid showers and tub bathing.
- Instruct the patient to perform normal activities, such as walking, sleeping, climbing stairs, sexual activity, bowel or urinary elimination, cigarette smoking, emotional upsets, and medications, and to record them in an activity log.
- Instruct the patient to wear loose-fitting clothing over the electrodes and not to disturb or disconnect the electrodes or wires.
- Instruct the patient regarding recording and pressing the button upon experiencing pain or discomfort.
- Advise the patient to report a light signal on the monitor, which indicates equipment malfunction or that an electrode has come off.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during and after the procedure.

Intratest:

- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in a supine position.
- Expose the chest. Shave excessive hair at the skin sites; cleanse thoroughly with alcohol and rub until red in color.
- Apply electropaste to the skin sites to provide conduction between the skin and electrodes, or apply disk electrodes that are prelubricated and disposable.
- Apply two electrodes on the manubrium (negative electrodes), one in the V_1 position (fourth intercostal space at the border of the right sternum), and one at the V_5 position (level of the fifth intercostal space at the midclavicular line, horizontally and at the left axillary line). A ground electrode is also placed and secured to the skin of the chest or abdomen.
- After checking to ensure that the electrodes are secure, attach the electrode cable to the monitor and the lead wires to the electrodes.
- Check the monitor for paper supply and battery, insert the tape, and turn on the recorder. Tape all wires to the chest, and place the belt or shoulder strap in the proper position.

Post-test:

- Gently remove the tape and other items securing the electrodes to the patient.
- Advise the patient to immediately report symptoms such as fast heart rate or difficulty breathing.
- Compare the activity log and tape recordings for changes during the monitoring period.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of

the test results, as appropriate. Educate the patient regarding access to counseling services.

- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include echocardiography and electrocardiogram.

HOMOCYSTEINE AND METHYLMALONIC ACID

SYNONYM/ACRONYM: N/A.

SPECIMEN: Serum (4 mL) collected in a red- or tiger-top tube if methylmalonic acid and homocysteine are to be measured together. Alternatively, plasma collected in a lavender-top (EDTA) tube may be acceptable for the homocysteine measurement. The laboratory should be consulted before specimen collection because specimen type may be method dependent. Care must be taken to use the same type of collection container if serial measurements are to be taken.

REFERENCE VALUE: (Method: Chromatography) Homocysteine: 8 to 20 μmol/L; methylmalonic acid: 80 to 560 μmol/L.

DESCRIPTION & RATIONALE: Homocysteine is an amino acid formed from methionine. Normally homocysteine is rapidly remetabolized in a biochemical pathway that requires vitamin B_{12} and folate, preventing the buildup of homocysteine in the blood. Excess levels damage the endothelial lining of blood vessels; change coagulation factor levels, increasing the risk of blood clot formation; prevent smaller arteries from dilating, increasing the risk of plaque formation; cause platelet aggregation; and cause smooth muscle cells lining the arterial wall to multiply, promoting atherosclerosis.

Approximately one-third of patients with hyperhomocystinuria have normal fasting levels. Patients with a heterozygous biochemical enzyme defect in cystathionine B synthase or with a nutritional deficiency in vitamin B_6

can be identified through the administration of a methionine challenge or loading test. Specimens are collected while fasting and 2 hours later. An increase in homocysteine after 2 hours is indicative of hyperhomocystinuria. In patients with vitamin B_{12} deficiency, elevated levels of methylmalonic acid and homocysteine develop fairly early in the course of the disease. Unlike vitamin B_{12} levels, homocysteine levels will remain elevated for at least 24 hours after the start of vitamin therapy. This may be useful if vitamin therapy is inadvertently begun before specimen collection. Patients with folate deficiency, for the most part, will only develop elevated homocysteine levels. Hyperhomocystinemia due to folate deficiency in pregnant women is believed to increase the risk of neural tube defects. Elevated levels of homocysteine are thought to chemically damage the exposed neural tissue of the developing fetus. ■

INDICATIONS:

- Evaluate inherited enzyme deficiencies that result in homocystinuria
- Evaluate the risk for cardiovascular disease
- Evaluate the risk for venous thrombosis

RESULT

Increased in:

- Chronic renal failure
- Coronary artery disease
- Folic acid deficiency
- Homocystinuria
- Vitamin B_{12} deficiency

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase plasma homocysteine levels include anticonvulsants, cycloserine, hydralazine, isoniazid, methotrexate, penicillamine, phenelzine, and theophylline.
- Specimens should be kept at a refrigerated temperature and delivered immediately to the laboratory for processing.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to screen for risk of cardiovascular disease and stroke.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular and hematopoietic systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Cardiovascular and Hematopoietic System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.

- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen for combined methylmalonic acid and homocysteine studies in two 5-mL red- or tiger-top tubes. If only homocysteine is to be measured, a 5-mL lavender-top tube is acceptable.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Increased homocysteine levels may be associated with atherosclerosis and coronary artery disease. Nutritional therapy is recommended for individuals identified to be at high risk for developing coronary artery disease. If overweight, these patients should be encouraged to achieve a normal weight. The American Heart Association has Step 1 and Step 2 diets that may be helpful in achieving a goal of lowering total cholesterol and triglyceride levels. The Step 1 diet emphasizes a reduction in foods high in saturated fats and cholesterol. Red meats, eggs, and dairy products are the major sources of saturated fats and cholesterol. If triglycerides are also elevated, patients should be advised to eliminate or reduce alcohol and simple carbohydrates from their diet. The Step 2 diet recommends stricter reductions.
- *Nutritional considerations:* Diets rich in fruits, grains, and cereals, in addition to a multivitamin containing B_{12} and folate, may be recommended for patients with elevated homocysteine levels. Processed and refined foods should be kept to a minimum.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association *(http://www.americanheart.org).*
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

Related laboratory tests include antiarrhythmic drugs, apolipoprotein A, apolipoprotein B, aspartate aminotransferase, atrial natriuretic peptide, blood gases, B-type natriuretic peptide, calcium (blood and ionized), cholesterol (total, HDL, and LDL), complete blood count, C-reactive protein, creatine kinase and isoenzymes, folate, glucose, glycated hemoglobin, ketones, lactate dehydrogenase and isoenzymes, lipoprotein electrophoresis, magnesium, myoglobin, pericardial fluid, potassium, triglycerides, troponin, and vitamin B_{12}.

HOMOVANILLIC ACID

SYNONYM/ACRONYM: HVA.

SPECIMEN: Urine (10 mL) from a timed specimen collected in a clean plastic collection container with 6N HCl as a preservative.

REFERENCE VALUE: (Method: Chromatography)

Age	Conventional Units	SI Units
	Homovanillic acid	
		(Conventional Units × 5.49)
3–6 y	1.4–4.3 mg/24 h	8–24 μmol/24 h
7–10 y	2.1–4.7 mg/24 h	12–26 μmol/24 h
11–16 y	2.4–8.7 mg/24 h	13–48 μmol/24 h
Adult	1.4–8.8 mg/24 h	8–48 μmol/24 h
	Vanillylmandelic Acid	
		(Conventional Units × 5.05)
3–6 y	1.0–2.6 mg/24 h	5–13 μmol/24 h
7–10 y	2.0–3.2 mg/24 h	10–16 μmol/24 h
11–16 y	2.3–5.2 mg/24 h	12–26 μmol/24 h
Adult	1.4–6.5 mg/24 h	7–33 μmol/24 h

DESCRIPTION & RATIONALE: Homovanillic acid (HVA) is the main terminal metabolite of dopamine. Vanillylmandelic acid is a major metabolite of epinephrine and norepinephrine. Both of these tests should be evaluated together for the diagnosis of neuroblastoma. Excretion may

be intermittent; therefore, a 24-hour specimen is preferred. Creatinine is usually measured simultaneously to ensure adequate collection and to calculate an excretion ratio of metabolite to creatinine. ■

INDICATIONS:

- Assist in the diagnosis of pheochromocytoma, neuroblastoma, and ganglioblastoma
- Monitor the course of therapy

RESULT

Increased in:

- Ganglioblastoma
- Neuroblastoma
- Pheochromocytoma
- Riley-Day syndrome

Decreased in:

- Schizotypal personality disorders

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase HVA levels include acetylsalicylic acid, disulfiram, levodopa, pyridoxine, and reserpine.
- Drugs that may decrease HVA levels include moclobemide.
- All urine voided for the timed collection period must be included in the collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

Nursing Implications and Procedure

Pretest:

➤ Inform the patient that the test is used to diagnose neuroblastoma, pheochromocytoma, and ganglioblastoma and to monitor therapy.

➤ Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.

➤ Obtain a history of the patient's endocrine system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine System table.

➤ Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.

➤ Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.

➤ Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.

➤ Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

➤ *Sensitivity to social and cultural issues*, as well as concern for modesty, is important in providing psy-

chological support before, during, and after the procedure.

- If possible, and with medical direction, patients should withhold acetylsalicylic acid, disulfiram, pyridoxine, and reserpine for 2 days before specimen collection. Levodopa should be withheld for 2 weeks before specimen collection.
- There are no food or fluid restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with medication restrictions; assure that specified medications, with medical direction, have been restricted for at least 2 days prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection.

Timed specimen:

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 a.m. and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container's label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual medications, as directed by the health care practitioner.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or

address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include carcinoembryonic antigen, catecholamines (blood and urine), metanephrines, and vanillylmandelic acid.

HUMAN CHORIONIC GONADOTROPIN

SYNONYMS/ACRONYMS: Chorionic gonadotropin, pregnancy test, HCG, hCG, β-HCG, β-subunit HCG.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Immunoassay)

	Conventional Units	SI Units (Conventional Units × 1)
Males and nonpregnant females	Less than 5 mIU/mL	Less than 5 IU/L
Pregnant females by week of gestation:		
Less than 1 wk	5–50 mIU/mL	5–50 IU/L
2 wk	50–500 mIU/mL	50–500 IU/L
3 wk	100–10,000 mIU/mL	100–10,000 IU/L
4 wk	1,000–30,000 mIU/mL	1,000–30,000 IU/L
5 wk	3,500–115,000 mIU/mL	3,500–115,000 IU/L
6–8 wk	12,000–270,000 mIU/mL	12,000–270,000 IU/L
12 wk	15,000–220,000 mIU/mL	15,000–220,000 IU/L

DESCRIPTION & RATIONALE: Human chorionic gonadotropin (HCG) is a hormone secreted by the placenta beginning 8 to 10 days after conception, which coincides with implantation of the fertilized ovum. It stimulates secretion of progesterone by the corpus luteum. HCG levels peak at 8 to 12 weeks of gestation and then fall to less than 10% of first trimester

levels by the end of pregnancy. By postpartum week 2, levels are undetectable. HCG levels increase at a slower rate in ectopic pregnancy and spontaneous abortion than in normal pregnancy; a low rate of change between serial specimens is predictive of a nonviable fetus. As assays improve in sensitivity over time, ectopic pregnancies are increasingly being identified before rupture. HCG is used along with estriol and α_1-fetoprotein in prenatal screening for neural tube defects. These prenatal measurements are also known as *triple markers.* Serial measurements are needed for an accurate estimate of gestational stage and determination of fetal viability. Triple marker testing has also been used to screen for trisomy 21 (Down syndrome). (To compare HCG to other tests in the triple marker screening procedure, see monograph titled "α_1-Fetoprotein.") HCG is also produced by some germ cell tumors. Most assays measure both the intact and free β-HCG subunit, but if HCG is to be used as a tumor marker, the assay must be capable of detecting both intact and free β-HCG. ■

INDICATIONS:

- Assist in the diagnosis of suspected HCG-producing tumors, such as choriocarcinoma, germ cell tumors of the ovary and testes, or hydatidiform moles
- Confirm pregnancy, assist in the diagnosis of suspected ectopic pregnancy, or determine threatened or incomplete abortion
- Determine adequacy of hormonal levels to maintain pregnancy
- Monitor effects of surgery or chemotherapy
- Monitor ovulation induction treatment
- Prenatally detect neural tube defects and trisomy 21 (Down syndrome)

RESULT

Increased in:

- Choriocarcinoma
- Ectopic HCG-producing tumors (stomach, lung, colon, pancreas, liver, breast)
- Erythroblastosis fetalis
- Germ cell tumors (ovary and testes)
- Hydatidiform mole
- Islet cell tumors
- Multiple gestation pregnancy
- Pregnancy

Decreased in:

- Ectopic pregnancy
- Incomplete abortion
- Intrauterine fetal demise
- Spontaneous abortion
- Threatened abortion

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may decrease HCG levels include epostane and mifepristone.
- Results may vary widely depending on the sensitivity and specificity of the assay. Performance of the test too early in pregnancy may cause false-negative results. HCG is composed of an α and a β subunit. The structure of the α subunit is essentially identical to the α subunit of follicle-stimulating hormone, luteinizing hormone, and thyroid-stimulating hormone. The structure of the β subunit differentiates HCG from the other hormones. False-positive results can therefore be obtained if the HCG assay does not detect β subunit.

Nursing Implications and Procedure

Pretest:

- Inform the patient, as appropriate, that the test is used to verify pregnancy, screen for neural tube defects, or detect HCG-secreting tumors.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine, immune, and reproductive systems and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine, Immune, and Reproductive System tables.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- *Social and cultural considerations:* Recognize anxiety related to abnormal test results, and encourage the family to seek counseling if concerned with pregnancy termination or to seek genetic counseling if a chromosomal abnormality is determined. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Decisions regarding elective abortion should take place in the presence of both parents. Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks and difficulties of delivering and raising a developmen-

tally challenged infant, as well as exploring other options (termination of pregnancy or adoption). It is also important to discuss feelings the mother and father may experience (e.g., guilt, depression, anger) if fetal abnormalities are detected.

- *Social and cultural considerations:* Offer support, as appropriate, to patients who may be the victims of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nonthreatening atmosphere for a discussion during which risks of sexually transmitted diseases are explained. It is also important to discuss problems the victim of sexual assault may experience (e.g., guilt, depression, anger) if there is possibility of pregnancy related to the assault.
- *Social and cultural considerations:* In patients with carcinoma, recognize anxiety related to test results and offer support. Provide teaching and information regarding the clinical implications of abnormal test results, as appropriate. Educate the patient regarding access to counseling services, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor the patient's condition and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include *Chlamydia* group antibody, chorionic villus biopsy, chromosome analysis, cytomegalovirus antibody, estradiol, fetal fibronectin, α_1-fetoprotein, hemwatocrit, hemoglobin, progesterone, rubella antibody, rubeola antibody, syphilis serology, toxoplasma antibody, and white blood cell count.

HUMAN IMMUNODEFICIENCY VIRUS TYPE 1 AND TYPE 2 ANTIBODIES

SYNONYM/ACRONYM: HIV-1/HIV-2.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Enzyme immunoassay) Negative.

DESCRIPTION & RATIONALE: Human immunodeficiency virus (HIV) is the etiologic agent of acquired immunodeficiency syndrome (AIDS) and is transmitted through bodily secretions, especially by blood or sexual contact. The virus preferentially binds to the T4 helper lymphocytes and replicates within the cells. Current assays detect several viral proteins. Positive results should be confirmed by Western blot assay. This test is routinely recommended as part of a prenatal workup and is required for evaluating donated blood units before release for transfusion. ■

INDICATIONS:

- Evaluate donated blood units before transfusion
- Perform as part of prenatal screening
- Screen organ transplant donors
- Test individuals who have documented and significant exposure to other infected individuals
- Test exposed high-risk individuals for detection of antibody (e.g., persons with multiple sex partners, persons with a history of other sexually transmitted diseases, intravenous drug users, infants born to infected mothers, allied health care workers, public service employees who have contact with blood and blood products)

RESULT

Positive findings in: HIV-1 or HIV-2 infection

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may decrease HIV antibody levels include didanosine, dideoxycytidine, zalcitabine, and zidovudine.
- Nonreactive HIV test results occur during the acute stage of the disease, when the virus is present but antibodies have not sufficiently developed to be detected. It may take up to 6 months for the test to become positive. During this stage, the test for HIV antigen may not confirm an HIV infection.
- Test kits for HIV are very sensitive. As a result, nonspecific reactions may occur, leading to a false-positive result.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to test blood for the presence of antibodies to human inmmunodeficiency virus.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune and reproductive systems, a history of high-risk behaviors, and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Reproductive System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may

be some discomfort during the venipuncture.

- There are no food, fluid, or medication restrictions, unless by medical direction.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Warn the patient that false-positive results occur and that the absence of antibody does not guarantee absence of infection, because the virus may be latent or may not have produced detectable antibody at the time of testing.
- *Social and cultural considerations:* Recognize anxiety related to test results, and be supportive of impaired activity related to weakness, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for AIDS information provided by the National Institutes of Health *(http://www.aidsinfo.nih.gov)*.
- *Social and cultural considerations:* Counsel the patient, as appropriate, regarding risk of transmission and proper prophylaxis, and reinforce the importance of strict adherence to the treatment regimen.
- *Social and cultural considerations:* Inform patients that positive findings must be reported to local health department officials, who will question him or her regarding sexual partners.
- *Social and cultural considerations:* Offer support, as appropriate, to patients who may be the victims of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nonthreatening atmosphere for a discussion during which risks of sexually transmitted diseases are explained. It is also important to discuss problems the patient may experience (e.g., guilt, depression, anger).
- Inform the patient that retesting may be necessary.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or

address any concerns voiced by the patient or family.

➤ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

➤ Related laboratory tests include CD4/CD8 enumeration, *Chlamydia* group antibody, complete blood count, cytomegalovirus, hepatitis B antibody and antigen, hepatitis C antibody, human T-cell lymphotropic virus types I and II, β_2-microglobulin, skin culture, and syphilis serology.

HUMAN LEUKOCYTE ANTIGEN B27

SYNONYM/ACRONYM: HLA-B27.

SPECIMEN: Whole blood (5 mL) collected in green-top (heparin) or yellow-top (acid-citrate-dextrose [ACD]) tube.

REFERENCE VALUE: (Method: Flow cytometry) Negative (indicating absence of the antigen).

DESCRIPTION & RATIONALE: The human leukocyte antigens (HLAs) are gene products of the major histocompatibility complex, derived from their respective loci on the short arm of chromosome 6. There are more than 27 identified HLAs. HLA-B27 is an allele (one of two or more genes for an inheritable trait that occupy the same location on each chromosome, paternal and maternal) of the HLA-B locus. The presence of HLA-B27 is associated with several specific conditions, as listed later, but HLA-B27 should not be used as a screening test for these conditions. ■

INDICATIONS: Assist in diagnosing ankylosing spondylitis and Reiter's syndrome

RESULT

Positive findings in:

- Ankylosing spondylitis
- Juvenile rheumatoid arthritis
- Psoriatic arthritis
- Reiter's syndrome

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- The specimen should be stored at room temperature and should be received by the laboratory performing the assay within 24 hours of collection. It is highly recommended that the laboratory be contacted before specimen collection to avoid specimen rejection.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate ankylosing spondylitis and other disorders associated with HLA-B27.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune and musculoskeletal systems as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Musculoskeletal System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL green- or yellow-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and and fear of shortened life expectancy. These diseases can be moderately to severely debilitating, resulting in significant lifestyle changes. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Inform the patient that false-positive test results occur and that

retesting may be required. Answer any questions or address any concerns voiced by the patient or family.

➤ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

➤ A related laboratory test is rheumatoid factor.

HUMAN T-LYMPHOTROPIC VIRUS TYPE I AND TYPE II ANTIBODIES

SYNONYM/ACRONYM: HTLV-I/HTLV-II.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Enzyme immunoassay) Negative.

DESCRIPTION & RATIONALE: Human T-lymphotropic virus type I (HTLV-I) and type II (HTLV-II) are two closely related retroviruses known to remain latent for extended periods before becoming reactive. The viruses are transmitted by sexual contact, contact with blood, placental transfer from mother to fetus, or ingestion of breast milk. As with human immunodeficiency virus type 1 (HIV-1) and type 2 (HIV-2), HTLV targets the T4 lymphocytes. The disease is uncommon in the United States, but retrospective studies conducted by the American Red Cross demonstrated that a small percentage of transfusion recipients became infected by HTLV-positive blood. The results of this study led to a requirement that all donated blood units be tested for HTLV-I/HTLV-II before release for transfusion. ■

INDICATIONS:

- Distinguish HTLV-I/HTLV-II infection from spastic myelopathy
- Establish HTLV-I as the causative agent in adult lymphoblastic (T-cell) leukemia
- Evaluate donated blood units before transfusion
- Evaluate HTLV-II as a contributing cause of chronic neuromuscular disease

RESULT

Positive findings in: HTLV-I/HTLV-II infection

CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to test blood for the presence of antibodies that would indicate past or current HTLV infection.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune system, a history of high-risk behaviors, and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune System table.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Warn the patient that false-positive results occur and that the absence of antibody does not guarantee absence of infection, because the virus may be latent or not have produced detectable antibody at the time of testing.
- *Social and cultural considerations:* Recognize anxiety related to test results, and be supportive of impaired activity related to weakness, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of positive test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

- *Social and cultural considerations:* Counsel the patient, as appropriate, regarding risk of transmission and proper prophylaxis, and reinforce the importance of strict adherence to the treatment regimen.
- Inform the patient that the presence of HTLV-I/HTLV-II antibodies precludes blood donation, but it does not mean that leukemia or a neurologic disorder is present or will develop.
- Inform the patient that subsequent retesting may be necessary.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include complete blood count, hepatitis B, C, and D antigens and antibodies, and HIV-1/HIV-2.

5-HYDROXYINDOLEACETIC ACID

SYNONYM/ACRONYM: 5-HIAA.

SPECIMEN: Urine (10 mL) from a timed specimen collected in a clean plastic collection container with boric acid as a preservative.

REFERENCE VALUE: (Method: High-pressure liquid chromatography)

Conventional Units	SI Units (Conventional Units × 5.23)
2–7 mg/24 h	10.5–36.6 μmol/24 h

DESCRIPTION & RATIONALE: Because 5-hydroxyindoleacetic acid (5-HIAA) is a metabolite of serotonin, 5-HIAA levels reflect plasma serotonin concentrations. 5-HIAA is excreted in the urine. Increased urinary excretion occurs in the presence of carcinoid tumors. This test, which replaces serotonin measurement, is most accurate when obtained from a 24-hour urine specimen. ■

INDICATIONS: Detect early, small, or intermittently secreting carcinoid tumors

Result

Increased in:

- Celiac and tropical sprue
- Cystic fibrosis
- Foregut and midgut carcinoid tumors
- Oat cell carcinoma of the bronchus
- Ovarian carcinoid tumors
- Whipple's disease

Decreased in:

- Depressive illnesses
- Hartnup disease
- Mastocytosis
- Phenylketonuria
- Renal disease
- Small intestine resection

Critical Values: N/A

Interfering Factors:

- Drugs that may increase 5-HIAA levels include acetaminophen, cisplatin, ephedrine, fluorouracil, cough syrups containing glyceryl guaiacolate, melphalan, mephenesin, methocarbamol, naproxen, phenacetin, pindolol, and rauwolfia alkaloids.
- Drugs that may decrease 5-HIAA levels include corticotropin, ethanol, imipramine, isoniazid, levodopa, methenamine, methyldopa, monoamine oxidase inhibitors, and phenothiazines.
- Foods containing serotonin, such as avocados, bananas, chocolate, eggplant, pineapples, plantain, red plums, tomatoes, and walnuts, can falsely elevate levels if ingested within 4 days of specimen collection.
- Severe gastrointestinal disturbance or diarrhea can interfere with test results.
- Failure to collect all the urine and store the specimen properly during the 24-hour test period invalidates the results.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to diagnose carcinoid tumors.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine, gastrointestinal, and immune system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine, Gastrointestinal, and Immune System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
- Inform the patient that all urine collected over a 24-hour period must be saved; if a preservative has been added to the container, instruct the patient not to discard the preservative. Instruct the patient not to void directly into the container. Instruct the patient to avoid defecating in the

collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom as a reminder to save all urine.

- Instruct the patient to void all urine into the collection device, then pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no fluid restrictions unless by medical direction.
- Inform the patient that foods and medications (herbs, nutritional supplements, and nutraceuticals) listed under "Interfering Factors" should be restricted by medical direction for at least 4 days before specimen collection.

Intratest:

- Ensure that the patient has complied with dietary and medication restrictions; assure foods and medications listed under "Interfering Factors" have been restricted for at least 4 days prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

Timed specimen:

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started, and add this last voiding to the container.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage. Conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the specimen collection container's label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results. Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, as directed by the health care practitioner. Consideration may be given to niacin supplementation and increased protein, if appropriate, for patients with abnormal findings. In

some cases, the tumor may divert dietary tryptophan to serotonin, resulting in pellagra.

- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- A related laboratory test is biopsy of the affected tissue.

HYPERSENSITIVITY PNEUMONITIS SEROLOGY

SYNONYM/ACRONYM: Farmer's lung disease serology, extrinsic allergic alveolitis.

SPECIMEN: Serum (2 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Immunodiffusion) Negative.

DESCRIPTION & RATIONALE: Hypersensitivity pneumonitis is a respiratory disease caused by the inhalation of organisms from an organic source. Affected and symptomatic individuals will demonstrate acute bronchospastic reaction 4 to 6 hours after exposure to the offending antigen. Inhalation of the antigen stimulates the production of immunoglobulin (Ig) G antibodies. The combination of immunecomplexing and cell-mediated immunopathogenesis results in a chronic granulomatous pneumonitis of the interstitial space of the lung. Hypersensitivity pneumonitis serology includes detection of antibodies to *Aspergillus fumigatus, Micropolyspora faeni, Thermoactinomyces vulgaris,* and *T. candidus.* A negative test result does not rule out hypersensitivity pneumonitis as a possible diagnosis, nor

does a positive test result confirm the diagnosis. Also, individuals with a positive test result may not exhibit the typical symptoms, and patients with severe symptoms may not have detectable levels of antibody while their disease is inactive. To confirm the diagnosis, it is necessary to obtain a sputum culture and chest x-rays. ■

INDICATIONS: Assist in establishing a diagnosis of hypersensitivity pneumonitis in patients experiencing fever, chills, and dyspnea after repeated exposure to moist organic sources

RESULT

Increased in: Hypersensitivity pneumonitis

CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to establish a diagnosis of hypersensitivity pneumonitis.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune and respiratory systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Respiratory System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.

- *Nutritional considerations:* Positive test results may be associated with respiratory disease. Malnutrition is commonly seen in patients with severe respiratory disease for reasons including fatigue and lack of appetite. The importance of following the prescribed diet should be stressed to the patient and/or caregiver.
- Instruct the patient in preventive measures for protecting his or her lungs (e.g., avoid contact with persons who have respiratory or other infections, avoid use of tobacco, avoid highly polluted areas as well as work environments with hazards such as fumes, dust, and other respiratory pollutants).
- Instruct the patient in deep breathing and pursed-lip breathing to enhance breathing patterns, as appropriate.
- Inform the patient of smoking cessation programs, as appropriate.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to lack of respiratory function, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Lung Association *(http://www.lungusa.org)*.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related tests include allergen-specific IgE, arterial/alveolar oxygen ratio, chest x-ray, complete blood count, eosinophil count, lung biopsy, and sputum culture.

HYSTEROSALPINGOGRAPHY

SYNONYMS/ACRONYM: Uterography, uterosalpingography, hysterogram.

AREA OF APPLICATION: Uterus and fallopian tubes.

CONTRAST: Iodinated contrast medium.

DESCRIPTION & RATIONALE: Hysterosalpingography is generally performed as part of an infertility study to identify anatomic abnormalities of the uterus or occlusion of the fallopian tubes. The procedure allows visualization of the uterine cavity, fallopian tubes, and peritubal area after the injection of contrast medium into the cervix. The contrast medium should flow through the uterine cavity, through the fallopian tubes, and into the peritoneal cavity, where it can be absorbed if no obstruction exists. Passage of the contrast medium through the tubes may clear mucous plugs, straighten kinked tubes, or break up adhesions, thus restoring fertility. This procedure is also used to evaluate the fallopian tubes after tubal ligation and to evaluate the results of reconstructive surgery. Risks include uterine perforation, exposure to radiation, infection, allergic reaction to contrast medium, bleeding, and pulmonary embolism. ■

INDICATIONS:

- Confirm the presence of fistulas or adhesions
- Confirm tubal abnormalities such as adhesions and occlusions
- Confirm uterine abnormalities such as congenital malformation, traumatic injuries, or the presence of foreign bodies
- Detect bicornate uterus
- Evaluate adequacy of surgical tubal ligation and reconstructive surgery

RESULT

Normal Findings:

- Contrast medium flowing freely into the fallopian tubes and not leaking from the uterus
- Normal position, shape, and size of the uterine cavity

Abnormal Findings:

- Bicornate uterus
- Developmental abnormalities
- Extrauterine pregnancy
- Internal scarring
- Kinking of the fallopian tubes due to adhesions
- Partial or complete blockage of fallopian tube(s)
- Tumors
- Uterine cavity anomalies
- Uterine fistulas
- Uterine masses or foreign body
- Uterine fibroid tumors (leiomyomas)

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients with bleeding disorders.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.
- Patients with menses, undiagnosed vaginal bleeding, or pelvic inflammatory disease.

- Young patients (17 years and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.

Factors that may impair clear imaging:

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Insufficient injection of contrast medium
- Excessive traction during the test or tubal spasm, which may cause the appearance of a stricture in an otherwise normal fallopian tube

Other considerations:

- Excessive traction during the test may displace adhesions, making the fallopian tubes appear normal.
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the uterus and fallopian tubes.
- Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, and dyes.
- Obtain a history of the patient's reproductive and genitourinary systems, and results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Reproductive and Genitourinary System tables.
- Ensure that this procedure is performed before an upper gastrointestinal study or barium swallow.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain

related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Explain to the patient that she may feel temporary sensations of nausea, dizziness, slow heartbeat, and menstrual-like cramping during the procedure and shoulder pain from subphrenic irritation from the contrast medium as it spills into the peritoneal cavity. Explain the purpose of the test and how the procedure is performed. Inform the patient that the procedure is performed in a radiology department, usually by a health care practitioner and support staff, and takes approximately 30 to 60 minutes.

- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during and after the procedure.
- Instruct the patient to fast and restrict fluids for 8 hours prior to the procedure.
- Patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hours after the test. Failure to do so may result in lactic acidosis.
- Instruct the patient to take a laxative or a cathartic, as ordered, on the evening before the examination.
- Instruct the patient to remove jewelry (including watches), credit cards, and other metallic objects.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that the patient has complied with dietary and medication restrictions and pretesting preparations for at least 6 hours prior to the procedure. Ensure the patient has removed all external metallic objects prior to the procedure.
- Assess for completion of bowel preparation according to the institution's procedure. Administer enemas or suppositories on the morning of the test, as ordered.
- Have emergency equipment readily available.
- Patients are given a gown and robe to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Remove any wires connected to electrodes, if allowed.
- Place the patient in a lithotomy position on the fluoroscopy table.
- A kidney, ureter, and bladder (KUB) film is taken to ensure that no stool, gas, or barium will obscure visualization of the uterus and fallopian tubes.
- A speculum is inserted into the vagina, and contrast medium is introduced into the uterus through the cervix via a cannula, after which both fluoroscopic and radiographic films are taken.
- To take oblique views, the table may be tilted or the patient may be asked to change position during the procedure.
- The results are recorded manually, on film, or by automated equipment in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the health care practitioner.
- Monitor for reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Monitor urinary output after the procedure. Decreased urine output may indicate impending renal failure.

- Evaluate the patient for signs of infection, such as pain, fever, increased pulse rate, chills, flushing, abdominal pain, tachycardia, or muscle aches.
- Inform the patient that a vaginal discharge is common and that it may be bloody, lasting 1 to 2 days after the test.
- Inform the patient that dizziness and cramping may follow this procedure, and that analgesia may be given if there is persistent cramping. Instruct the patient to contact the health care practitioner in the event of severe cramping or profuse bleeding.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the abdomen, kidney and urine bladder studies, magnetic resonance imaging of the abdomen, and ultrasound of the pelvis.

IMMUNOFIXATION ELECTROPHORESIS, BLOOD AND URINE

SYNONYM/ACRONYM: IFE.

SPECIMEN: Serum (1 mL) collected in a red-top tube. Urine (10 mL) from a random collection in a clean plastic container.

REFERENCE VALUE: (Method: Immunoprecipitation combined with electrophoresis) Test results are interpreted by a pathologist. Normal placement and intensity of staining provide information about the immunoglobulin bands.

DESCRIPTION & RATIONALE: Immunofixation electrophoresis (IFE) is a qualitative technique that provides a detailed separation of individual immunoglobulins according to their electrical charges. Abnormalities are revealed by changes produced in the individual bands, such as displace-

ment, color, or absence of color. Urine IFE has replaced the Bence Jones screening test for light chains. IFE has replaced immunoelectrophoresis because it is more sensitive and easier to interpret. ■

INDICATIONS:

- Assist in the diagnosis of multiple myeloma and amyloidosis
- Assist in the diagnosis of suspected immunodeficiency
- Assist in the diagnosis of suspected immunoproliferative disorders, such as multiple myeloma and Waldenström's macroglobulinemia
- Identify biclonal or monoclonal gammopathies
- Identify cryoglobulinemia
- Monitor the effectiveness of chemotherapy or radiation therapy

RESULT: See monograph titled "Immunoglobulins A, D, G, and M."

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase immunoglobulin levels include asparaginase, cimetidine, and narcotics.
- Drugs that may decrease immunoglobulin levels include dextran, oral contraceptives, methylprednisolone (high doses), and phenytoin.
- Chemotherapy and radiation treatments may alter the width of the bands and make interpretation difficult.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assess the immune system with respect to the type and quantity of immunoglobulins in blood and urine.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic and immune systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic and Immune System tables.
- Note any recent procedures that can interfere with test results. Assess whether the patient received any vaccinations or immunizations within the last 6 months or any blood or blood components within the last 6 weeks.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device.
- Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen.

Place a sign in the bathroom to remind the patient to save all urine.

- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, date, and time of collection.

Blood:

- Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.

Urine:

Clean-catch specimen:

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Blood or urine:

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include bone marrow biopsy, lymph node biopsy, complete blood count with examination of peripheral smear, quantitative immunoglobulin levels, protein quantitative (blood and urine) and fractions, and urinalysis.

IMMUNOGLOBULIN E

SYNONYM/ACRONYM: IgE.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 10)
Newborn	Less than 12 IU/mL	Less than 120 mg/L
Less than 1 y	Less than 50 IU/mL	Less than 500 mg/L
2–4 y	Less than 100 IU/mL	Less than 1000 mg/L
5 y and older	Less than 300 IU/mL	Less than 3000 mg/L

DESCRIPTION & RATIONALE: Immunoglobulin E (IgE) is an antibody whose primary response is to allergic reactions and parasitic infections. Most of the body's IgE is bound to specialized tissue cells; little is available in the circulating blood. IgE binds to the membrane of special granulocytes called *basophils* in the circulating blood and *mast cells* in the tissues. Basophil and mast cell membranes have receptors for IgE. Mast cells are abundant in the skin and the tissues lining the respiratory and alimentary tracts. When IgE antibody becomes cross-linked with antigen/allergen, the release of histamine, heparin, and other chemicals from the granules in the cells is triggered. A sequence of events follows activation of IgE that affects smooth muscle contraction, vascular permeability, and inflammatory reactions. The inflammatory response allows proteins from the bloodstream to enter the tissues. Helminths (worm parasites) are especially susceptible to immunoglobulin-mediated cytotoxic chemicals. The inflammatory reaction proteins attract macrophages from the circulatory system and granulocytes, such as eosinophils, from circulation and bone marrow. Eosinophils also contain enzymes effective against the parasitic invaders. ■

INDICATIONS: Assist in the evaluation of allergy and parasitic infection

RESULT

Increased in:

- Alcoholism
- Allergy
- Asthma
- Bronchopulmonary aspergillosis

- Dermatitis
- Eczema
- Hay fever
- IgE myeloma
- Parasitic infestation
- Rhinitis
- Sinusitis
- Wiskott-Aldrich syndrome

Decreased in:

- Advanced carcinoma
- Agammaglobulinemia
- Ataxia-telangiectasia
- IgE deficiency

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may cause a decrease in IgE levels include phenytoin and tryptophan.
- Penicillin G has been associated with increased IgE levels in some patients with drug-induced acute interstitial nephritis.
- Normal IgE levels do not eliminate allergic disorders as a possible diagnosis.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assess IgE levels in order to identify the presence of an allergic or inflammatory immune system response.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune and respiratory systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Respiratory System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and neutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually

or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- *Nutritional considerations:* Increased IgE levels may be associated with allergy. Consideration should be given to diet if the patient has food allergies.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the patient's condition and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include allergen-specific IgE, alveolar/arterial gradient and arterial/alveolar oxygen ratio, blood gases, complete blood count, eosinophil count, hypersensitivity pneumonitis, and theophylline.

IMMUNOGLOBULINS A, D, G, AND M

SYNONYMS/ACRONYMS: IgA, IgD, IgG, and IgM.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Nephelometry)

Age	Conventional Units	SI Units
	Immunoglobulin A	
		(Conventional Units × 0.01)
Newborn	1–4 mg/dL	0.01–0.04 g/L
1–9 mo	2–80 mg/dL	0.02–0.80 g/L
10–12 mo	15–90 mg/dL	0.15–0.90 g/L
2–3 y	18–150 mg/dL	0.18–1.50 g/L
4–5 y	25–160 mg/dL	0.25–1.60 g/L
6–8 y	35–200 mg/dL	0.35–2.00 g/L
9–12 y	45–250 mg/dL	0.45–2.50 g/L
Older than 12 y	40–350 mg/dL	0.40–3.50 g/L

Age	Conventional Units	SI Units
	Immunoglobulin D	
		(Conventional Units × 10)
Newborn	Greater than 2 mg/dL	Greater than 20 mg/L
Adult	Less than 15 mg/dL	Less than 150 mg/L
	Immunoglobulin G	
		(Conventional Units × 0.01)
Newborn	650–1600 mg/dL	6.5–16 g/L
1–9 mo	250–900 mg/dL	2.5–9 g/L
10–12 mo	290–1070 mg/dL	2.9–10.7 g/L
2–3 y	420–1200 mg/dL	4.2–12 g/L
4–6 y	460–1240 mg/dL	4.6–12.4 g/L
Greater than 6 y	650–1600 mg/dL	6.5–16 g/L
	Immunoglobulin M	
		(Conventional Units × 0.01)
Newborn	Less than 25 mg/dL	Less than 0.25 g/L
1–9 mo	20–125 mg/dL	0.2–1.25 g/L
10–12 mo	40–150 mg/dL	0.4–1.5 g/L
2–8 y	45–200 mg/dL	0.45–2.0 g/L
9–12 y	50–250 mg/dL	0.5–2.5 g/L
Greater than 12 y	50–300 mg/dL	0.5–3.0 g/L

DESCRIPTION & RATIONALE: Immunoglobulins A, D, E, G, and M are made by plasma cells in response to foreign particles. Immunoglobulins neutralize toxic substances, support phagocytosis, and destroy invading microorganisms. They are made up of heavy and light chains. Immunoglobulins produced by the proliferation of a single plasma cell (clone) are called *monoclonal*. Polyclonal increases result when multiple cell lines produce antibody. IgA is found mainly in secretions such as tears, saliva, and breast milk. It is believed to protect mucous membranes from viruses and bacteria. The function of IgD is not well understood. For details on IgE, see the monograph titled "Immunoglobulin E." IgG is the predominant serum immunoglobulin and is important in long-term defense against disease. It is the only antibody that crosses the placenta. IgM is the largest immunoglobulin, and it is the first antibody to react to an antigenic stimulus. IgM also forms natural antibodies, such as ABO blood group antibodies. The presence of IgM in cord blood is an indication of congenital infection. ■

INDICATIONS:

- Assist in the diagnosis of multiple myeloma
- Evaluate humoral immunity status
- Monitor therapy for multiple myeloma
- IgA: Evaluate patients suspected of IgA deficiency prior to transfusion. Evaluate anaphylaxis associated with the transfusion of blood and blood products (anti-

IgA antibodies may develop in patients with low levels of IgA, possibly resulting in anaphylaxis when donated blood is transfused)

Result

Increases in:

IgA:

- Polyclonal:
  - Chronic liver disease
  - Immunodeficiency states, such as Wiskott-Aldrich syndrome
  - Inflammatory bowel disease
  - Lower GI cancer
  - Rheumatoid arthritis
- Monoclonal:
  - IgA-type multiple myeloma

IgD:

- Polyclonal:
  - Certain liver diseases
  - Chronic infections
  - Connective tissue disorders
- Monoclonal:
  - IgD-type multiple myeloma

IgG:

- Polyclonal:
  - Autoimmune diseases, such as systemic lupus erythematosus, rheumatoid arthritis, and Sjögren's syndrome
  - Chronic liver disease
  - Chronic or recurrent infections
  - Intrauterine devices
  - Sarcoidosis
- Monoclonal:
  - IgG-type multiple myeloma
  - Leukemias
  - Lymphomas

IgM:

- Polyclonal:
  - Active sarcoidosis
  - Chronic hepatocellular disease
  - Collagen vascular disease
  - Early response to bacterial or parasitic infection
  - Hyper-IgM dysgammaglobulinemia
  - Rheumatoid arthritis
  - Variable in nephrotic syndrome
  - Viral infection (hepatitis or mononucleosis)
- Monoclonal:
  - Cold agglutinin hemolysis disease
  - Malignant lymphoma
  - Neoplasms (especially GI tract)
  - Reticulosis
  - Waldenström's macroglobulinemia

Decreases in:

IgA:

- Ataxia-telangiectasia
- Chronic sinopulmonary disease
- Genetic IgA deficiency

IgD:

- Genetic IgD deficiency
- Malignant melanoma of the skin
- Pre-eclampsia

IgG:

- Burns
- Genetic IgG deficiency
- Nephrotic syndrome
- Pregnancy

IgM:

- Burns
- Secondary IgM deficiency associated with IgG or IgA gammopathies

Critical Values: N/A

Interfering Factors:

- Drugs that may increase immunoglobulin levels include asparaginase, cimetidine, and narcotics.

- Drugs that may decrease immunoglobulin levels include dextran, oral contraceptives, methylprednisolone (high doses), and phenytoin.
- Chemotherapy, immunosuppressive therapy, and radiation treatments decrease immunoglobulin levels.
- Specimens with macroglobulins, cryoglobulins, or cold agglutinins tested at cold temperatures may give falsely low values.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assess the immune system with respect to the quantity of immunoglobulin levels present in the blood.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal, hematopoietic, immune, and musculoskeletal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Gastrointestinal, Hematopoietic, Immune, and Musculoskeletal System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Note any recent procedures that can interfere with test results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regard-

ing further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include bone marrow biopsy, blood groups and antibodies, complete blood count with evaluation of peripheral smear, immunofixation electrophoresis (blood and urine), protein quantitative (blood and urine) and fractions, and urinalysis.

IMMUNOSUPPRESSANTS: CYCLOSPORINE, METHOTREXATE

SYNONYMS/ACRONYM: Cyclosporine (Sandimmune), methotrexate (MTX, amethopterin, Folex, Rheumatrex), methotrexate sodium (Mexate).

SPECIMEN: Whole blood (1 mL) collected in lavender-top tube for cyclosporine. Serum (1 mL) collected in a red-top tube for methotrexate.

Immunosuppressant	Route of Administration	Recommended Collection Time
Cyclosporine	Oral	12 h after dose
Methotrexate	Oral	Varies according to dosing protocol
	Intramuscular	Varies according to dosing protocol

Important note: This information must be clearly and accurately communicated to avoid misunderstanding of the dose time in relation to the collection time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause of subtherapeutic levels, toxic levels, and misleading information used in calculation of future doses.

REFERENCE VALUE: (Method: Immunoassay)

	Therapeutic Dose		Half-Life	Volume of Distribution	Protein Binding	Excretion
	Conventional Units	*SI Units (Conventional Units × 0.832)*				
Cyclosporine	100–250 ng/mL Renal transplant	83–208 nmol/L	8–24 h	4–6 L/kg	90%	Renal
	100–400 ng/mL Cardiac transplant	83–333 nmol/L	8–24 h	4–6 L/kg	90%	Renal
	100–300 ng/mL Bone marrow transplant	83–250 nmol/L	8–24 h	4–6 L/kg	90%	Renal
	100–400 ng/mL Liver transplant	83–333 nmol/L	8–24 h	4–6 L/kg	90%	Renal
Methotrexate	0.01–5.00 μmol/L*		8–15 h	0.4–1.0 L/kg	50–70%	Renal

*Dependent on therapeutic approach.

DESCRIPTION & RATIONALE: Cyclosporine is an immunosuppressive drug used in the management of organ rejection, especially rejection of heart, liver, and kidney transplants. Its most serious side effect is renal impairment or renal failure. Methotrexate is a highly toxic drug that causes cell death by disrupting DNA synthesis.

Many factors must be considered in effective dosing and monitoring of therapeutic drugs, including patient age, weight, interacting medications, electrolyte balance, protein levels, water balance, and conditions that affect absorption and excretion; as well as foods, herbals, vitamins, and minerals that can either potentiate or inhibit the intended target concentration. ■

INDICATIONS

Cyclosporine:

- Assist in the management of treatments to prevent organ rejection
- Monitor for toxicity

Methotrexate:

- Monitor effectiveness of treatment of cancer and some autoimmune disorders
- Monitor for toxicity

RESULT

Normal levels	Therapeutic effect
Toxic levels	Adjust dose as indicated
Cyclosporine	Renal impairment
Methotrexate	Renal impairment

CRITICAL VALUES: It is important to note the adverse effects of toxic and subtherapeutic levels. Care must be taken to investigate signs and symptoms of too little and too much medication. Note and immediately report to the health care practitioner any critically increased values and related symptoms.

Cyclosporine: Greater than 400 ng/mL

Signs and symptoms of cyclosporine toxicity include increased severity of expected side effects, which include nausea, stomatitis, vomiting, anorexia, hypertension, infection, fluid retention, hypercalcemic metabolic acidosis, tremor, seizures, headache, and flushing. Possible interventions include close monitoring of blood levels to make dosing adjustments, inducing emesis (if orally ingested), performing gastric lavage (if orally ingested), withholding the drug, and initiating alternative therapy for a short time until the patient is stabilized.

Methotrexate: Greater than 5.00 μmol/L after 24 h; greater than 0.50 μmol/L after 48 h; greater than 0.05 μmol/L after 72 h

Signs and symptoms of methotrexate toxicity include increased severity of expected side effects, which include nausea, stomatitis, vomiting, anorexia, bleeding, infection, bone marrow depression, and, over a prolonged period of use, hepatotoxicity. The effect of methotrexate on normal cells can be reversed by administration of 5-formyltetrahydrofolate (citrovorum or leucovorin). 5-Formyltetrahydrofolate allows higher doses of methotrexate to be given.

INTERFERING FACTORS:

- Numerous drugs interact with cyclosporine and either increase cyclosporine levels or increase the risk of toxicity. These drugs include acyclovir, aminoglycosides, amiodarone, amphotericin B, anabolic steroids, cephalosporins, cimetidine, danazol, erythromycin, furosemide, ketoconazole, melphalan, methylprednisolone, miconazole, nonsteroidal anti-inflammatory drugs (NSAIDs), oral contraceptives, and trimethoprim-sulfamethoxazole.
- Drugs that may decrease cyclosporine levels include carbamazepine, ethotoin, mephenytoin, phenobarbital, phenytoin, primidone, and rifampin.
- Drugs that may increase methotrexate levels or increase the risk of toxicity include NSAIDs, probenecid, salicylate, and sulfonamides.
- Antibiotics may decrease the absorption of methotrexate.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to monitor for therapeutic and toxic drug levels.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's genitourinary and immune systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory

tests, refer to the Genitourinary and Immune System and Therapeutic/Toxicology table.

- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. Note the last time and dose of medication taken. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Consider recommended collection time with regard to dosing schedule. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a lavender-top tube for cyclosporine and a red-top tube for methotrexate.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Patients taking immunosuppressant therapy tend to have decreased appetites due to the side effects of the medication. Instruct patients to consume a variety of foods within the basic food groups, maintain a healthy weight, be physically active, limit salt intake, limit alcohol intake, and be a nonsmoker.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and offer support. Patients receiving these drugs usually have conditions that can be intermittently moderately to severely debilitating, resulting in significant lifestyle changes. Educate the patient regarding access to counseling services, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Explain to the patient the importance of following the medication regimen and give instructions regarding drug interactions. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient to be prepared to provide the pharmacist with a list of

other medications he or she is already taking in the event that the requesting health care practitioner prescribes a medication.

➤ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

➤ Related laboratory tests include blood urea nitrogen and creatinine.

INFECTIOUS MONONUCLEOSIS SCREEN

SYNONYMS/ACRONYM: Monospot, heterophil antibody test, IM serology.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Agglutination) Negative.

DESCRIPTION & RATIONALE: Infectious mononucleosis is caused by the Epstein-Barr virus (EBV). The incubation period is 10 to 50 days, and the symptoms last 1 to 4 weeks after the infection has fully developed. The hallmark of EBV infection is the presence of heterophil antibodies, also called *Paul-Bunnell-Davidsohn antibodies,* which are immunoglobulin M (IgM) antibodies that agglutinate sheep or horse red blood cells. The disease induces formation of abnormal lymphocytes in the lymph nodes; stimulates increased formation of heterophil antibodies; and is characterized by fever, cervical lymphadenopathy, tonsillopharyngitis, and hepatosplenomegaly. EBV is also thought to play a role in Burkitt's lymphoma, nasopharyngeal carcinoma, and chronic fatigue syndrome. If the results of the heterophil antibody screening test are negative and infectious mononucleosis is highly suspected, EBV-specific serology should be requested. ■

INDICATIONS: Assist in confirming infectious mononucleosis

RESULT

Positive findings in:
Infectious mononucleosis

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- False-positive results may occur in the presence of narcotic addiction, serum sickness, lymphomas, hepatitis,

leukemia, cancer of the pancreas, and phenytoin therapy.

- A false-negative result may occur if treatment was begun before antibodies developed or if the test was done less than 6 days after exposure to the virus.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the diagnosis of mononucleosis infection.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly. Obtain a history of exposure.
- Obtain a history of the patient's hepatobiliary and immune systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hepatobiliary and Immune System tables.
- Note any recent therapies that can interfere with test results.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Inform the patient that approximately 10% of all results are false-negative or false-positive. Inform the patient that signs and symptoms of infection include fever, chills, sore throat, enlarged lymph nodes, and fatigue. Self-care while the disease runs its course includes adequate fluid and nutritional intake along with sufficient rest. Activities that cause fatigue or stress should be avoided.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider

regarding further testing, treatment, or referral to another health care provider. Advise the patient to refrain from direct contact with others because the disease is transmitted through saliva. Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include complete blood count with peripheral blood smear evaluation.

INSULIN AND INSULIN RESPONSE TO GLUCOSE

SYNONYM/ACRONYM: N/A.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Radioimmunoassay)

	Insulin	SI Units (Conventional Units × 6.945)	Tolerance for Glucose (Hypoglycemia)
Fasting	Less than 25 mIU/L	Less than 174 pmol/L	65–115 mg/dL
30 min	30–230 mIU/L	208–1597 pmol/L	N/A
1 h	18–276 mIU/L	125–1917 pmol/L	Less than 200 mg/dL
2 h	16–166 mIU/L	111–1153 pmol/L	Less than 140 mg/dL
3 h	Less than 25 mIU/L	Less than 174 pmol/L	65–120 mg/dL
4 h	Less than 25 mIU/L	Less than 174 pmol/L	65–120 mg/dL
5 h	Less than 25 mIU/L	Less than 174 pmol/L	65–115 mg/dL

DESCRIPTION & RATIONALE: Insulin is secreted in response to elevated blood glucose, and its overall effect is to promote glucose use and energy storage. The insulin response test measures the rate of insulin secreted by the beta cells of the islets of Langerhans in the pancreas; it may be performed simultaneously with a 5-hour glucose tolerance test for hypoglycemia. ■

INDICATIONS:

- Assist in the diagnosis of early or developing non–insulin-dependent (type 2) diabetes, as indicated by excessive production of insulin in relation to blood glucose levels (best shown with glucose tolerance tests or 2-hour postprandial tests)
- Assist in the diagnosis of insulinoma, as indicated by sustained high levels of insulin and absence of blood glucose–related variations
- Confirm functional hypoglycemia, as indicated by circulating insulin levels appropriate to changing blood glucose levels
- Differentiate between insulin-resistant diabetes, in which insulin levels are high, and non–insulin-resistant diabetes, in which insulin levels are low
- Evaluate fasting hypoglycemia of unknown cause
- Evaluate postprandial hypoglycemia of unknown cause
- Evaluate uncontrolled insulin-dependent (type 1) diabetes

RESULT

Increased in:

- Acromegaly
- Alcohol use
- Cushing's syndrome
- Diabetes
- Excessive administration of insulin
- Insulin- and proinsulin-secreting tumors (insulinomas)
- Obesity
- Reactive hypoglycemia in developing diabetes
- Severe liver disease

Decreased in:

- Beta cell failure

CRITICAL VALUES: NA

INTERFERING FACTORS:

- Drugs and substances that may increase insulin levels include acetohexamide, alanine, albuterol, amino acids, beclomethasone, betamethasone, broxaterol, calcium gluconate, cannabis, chlorpropamide, cyclic AMP, glibornuride, glipizide, glisoxepide, glucagon, glyburide, ibopamine, insulin, insulin-like growth factor–I, oral contraceptives, pancreozymin, prednisolone, prednisone, rifampin, salbutamol, terbutaline, tolazamide, tolbutamide, trichlormethiazide, and verapamil.
- Drugs that may decrease insulin levels include acarbose, asparaginase, calcitonin, cimetidine, clofibrate, dexfenfluramine, diltiazem, doxazosin, enalapril, enprostil, ether, hydroxypropyl methylcellulose, insulin-like growth factor–I, metformin, niacin, nifedipine, nitrendipine, octreotide, phenytoin, propranolol, and psyllium.
- Administration of insulin or oral hypoglycemic agents within 8 hours of the test can lead to falsely elevated levels.
- Hemodialysis destroys insulin and affects test results.
- Recent radioactive scans or radiation can interfere with test results when radioimmunoassay is the test method.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the evaluation of fasting hypoglycemia.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine System table.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements and nutraceuticals. Note the last time and dose of medication taken. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that multiple specimens may be required. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- If a single sample is to be collected, the patient should have fasted and refrained, with medical direction, from taking insulin or other oral hypoglycemic agents for at least 8 hours before specimen collection.
- *Hypoglycemia:* Serial specimens for insulin levels are collected in conjunction with glucose levels after administration of a 100-g glucose load. The patient should be prepared as for a standard oral glucose tolerance test over a 5-hour period.
- There are no fluid restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with dietary or medication restrictions and other pretesting preparations; assure that food or medications have been restricted as instructed prior to the specific procedure's protocol.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.

- Instruct the patient to resume usual diet and medication, as directed by the health care practitioner.
- *Nutritional considerations:* Increased insulin levels may be associated with diabetes. The nutritional needs of each diabetic patient need to be determined individually (especially during pregnancy) by a health care practitioner trained in nutrition. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. There is no "diabetic diet"; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association.
- Impaired glucose tolerance may be associated with diabetes. Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, as appropriate, that good glycemic control delays the onset of and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Diabetes Association *(http://www.diabetes.org)*.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include C-peptide, fructosamine, glucose, glucose tolerance tests, glycated hemoglobin, insulin antibodies, and microalbumin.

INSULIN ANTIBODIES

SYNONYM/ACRONYM: N/A.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Radioimmunoassay) Less than 3%; includes binding of human, beef, and pork insulin to antibodies in patient's serum.

DESCRIPTION & RATIONALE: The most common anti-insulin antibody is immunoglobulin (Ig) G, but IgA, IgM, IgD, and IgE antibodies also have anti-insulin properties. These antibodies usually do not cause clinical problems, but they may complicate insulin assay testing. IgM is thought to participate in insulin resistance and IgE in insulin allergy. Improvements in the purity of animal insulin and increased use of human insulin have resulted in a significant decrease in the incidence of insulin antibody formation. ■

INDICATIONS:

- Assist in confirming insulin resistance
- Assist in determining if hypoglycemia is caused by insulin abuse
- Assist in determining insulin allergy

RESULT

- Factitious hypoglycemia
- Insulin allergy or resistance
- Polyendocrine autoimmune syndromes
- Steroid-induced diabetes (a side effect of treatment for systemic lupus erythematosus)

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS: Recent radioactive scans or radiation can interfere with test results when radioimmunoassay is the test method.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the prediction, diagnosis, and management of type I diabetes.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine and immune systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine and Immune System tables.
- Note any recent procedures that can interfere with test results.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. Note the last time and dose of medication taken. The requesting health care practitioner and laboratory should be advised if the patient is regularly using these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the

patient to breathe normally and to avoid unnecessary movement.

- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient to resume usual diet and medication, as directed by the health care practitioner.
- *Nutritional considerations:* The nutritional needs of each diabetic patient need to be determined individually (especially during pregnancy) by a health care practitioner trained in nutrition. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. There is no "diabetic diet"; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association.
- Impaired glucose tolerance may be associated with diabetes. Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, as appropriate, that good glycemic control delays the onset of and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Diabetes Association *(http://www.diabetes.org)*.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include C-peptide, glucose, glucose tolerance tests, and insulin.

INTRAOCULAR MUSCLE FUNCTION

SYNONYMS/ACRONYMS: IOM function.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION & RATIONALE: Evaluation of ocular motility is performed to detect and measure muscle imbalance in conditions classified as heterotropias or heterophorias. This evaluation is performed in a manner to assess fixation of each eye, alignment of both eyes in all directions, and the ability of both eyes to work together binocularly. Heterophorias are latent ocular deviations kept in check by the binocular power of fusion, and made intermittent by disrupting fusion. Heterotropias are conditions that manifest constant ocular deviations. The prefixes eso- (tendency for the eye to turn in), exo- (tendency for the eye to turn out), and hyper- (tendency for one eye to turn up) indicate the direction in which the affected eye moves spontaneously. *Strabismus* is the failure of both eyes to spontaneously fixate on the same object because of a muscular imbalance (crossed eyes). *Amblyopia,* or lazy eye, is a term used for loss of vision in one or both eyes that cannot be attributed to an organic pathologic condition of the eye or optic nerve. There are six extraocular muscles in each eye whose movement is controlled by three nerves. The actions of the muscles vary depending on the position of the eye when they become innervated. The cover test is commonly used because it is reliable, easy to perform, and does not require special equipment. The cover test method is described in this monograph. Another method for evaluation of ocular muscle function is the corneal light reflex test. It is useful with patients who cannot cooperate for prism cover testing or for patients who have poor fixation. ■

INDICATIONS:

- Detection and evaluation of extraocular muscle imbalance

RESULT

The examiner should determine the range of ocular movements in all gaze positions, usually to include up and out, in, down and out, up and in, down and in, and out. Limited movements in gaze position can be recorded semiquantitatively as –1 (minimal), –2 (moderate), –3 (severe), or –4 (total).

Normal Findings:

- Normal range of ocular movements in all gaze positions.

Abnormal Findings:

- Amblyopia
- Heterophorias
- Heterotropias
- Strabismus

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair the results of the examination:

- Inability of the patient to cooperate and remain still during the test because of age, significant pain, or mental status may interfere with the test results.
- Rubbing or squeezing the eyes may affect results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure evaluates extraocular muscle function.
- Obtain a history of the patient's complaints, including a list of known allergens.
- Obtain a history of the patient's known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- Obtain a history of results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that no discomfort will be experienced during the test. Inform the patient that a technician, optometrist, orthoptist, or physician performs the test, in a quiet room, and that to evaluate both eyes, the test can take 2 to 4 minutes.
- Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- One eye is tested at a time. The patient is given a fixation point, usually the testing personnel's index finger. An object, such as a small toy, can be used to ensure fixation in pediatric patients. The patient is asked to follow the fixation point with his or her gaze in the direction the fixation point moves. When testing is completed, the procedure is repeated using the other eye. The procedure is performed at distance and near, first with and then without corrective lenses.
- The results are recorded manually for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- A written report of the examination will be completed by a health care practitioner specializing in this

branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.

- Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss, perceived loss of driving privileges, or the possibility of requiring corrective lenses (self-image).
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Educate the patient, as appropriate, that he or she may be referred for special therapy to correct the anomaly, which may include glasses, prisms, eye exercises, eye patches, or chemical patching with drugs that modify the focusing power of the eye. The patient and family should be educated that the chosen therapy involves a process of mental retraining. The mode of therapy in itself does not correct vision. It is the process by which the brain becomes readapted to accept, receive, and store visual images received by the eye that results in vision correction. Therefore, the patient must be prepared to be alert, cooperative, and properly motivated. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include refraction and slit-lamp biomicroscopy.

INTRAOCULAR PRESSURE

SYNONYMS/ACRONYMS: IOP.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION & RATIONALE: The pressure of the eye depends on a number of factors. The two most significant are the amount of aqueous humor present in the eye and the circumstances by which it leaves the eye. Other physiologic variables that affect intraocular pressure (IOP) include respiration, pulse, and the degree of hydration of the body. Individual eyes respond to intraocular pressures differently. Some can tolerate high pressures (20 to 30 mm Hg), and some will incur optic nerve damage at lower pressures. With respiration, variations of up to 4 mm Hg in IOP can occur, and changes of 1 to 2 mm Hg occur with every pulsation of the central

retinal artery. IOP is measured with a tonometer; normal values indicate the pressure at which no damage is done to the intraocular contents.

The rate of fluid leaving the eye, or its ability to leave the eye unimpeded, is the most important factor regulating IOP. There are three primary conditions that result in occlusion of the outflow channels for fluid. The most common condition is open-angle glaucoma, in which the diameter of the openings of the trabecular meshwork becomes narrowed, resulting in an increased IOP due to an increased resistance of fluid moving out of the eye. In secondary glaucoma, the trabecular meshwork becomes occluded by tumor cells, pigment, red blood cells in hyphema, or other material. Additionally, the obstructing material may cover parts of the meshwork itself, as with scar tissue or other types of adhesions that form after severe iritis, an angle closure glaucoma attack, or a central retinal vein occlusion. The third condition impeding fluid outflow in the trabecular channels occurs with pupillary block, most commonly associated with primary angle-closure glaucoma. In eyes predisposed to this condition, dilation of the pupil causes the iris to fold up like an accordion against the narrow-angle structures of the eye. Fluid in the posterior chamber has difficulty circulating into the anterior chamber; therefore, pressure in the posterior chamber increases, causing the iris to bow forward and obstruct the outflow channels even more. Angle-closure attacks occur quite suddenly and therefore do not give the eye a chance to adjust itself to the sudden increase in pressure. The eye becomes very red, the cornea edematous (patient may report seeing halos), and the pupil fixed and dilated, accompanied by a complaint of moderate pain. Pupil dilation can be initiated by emotional arousal or fear, conditions in which the eye must adapt to darkness (movie theaters), or mydriatics. Angle-closure glaucoma is an ocular emergency that is resolved by a peripheral iridectomy to allow movement of fluid between the anterior and posterior chambers. This procedure constitutes removal of a portion of the peripheral iris either by surgery or by use of an argon or yttrium-aluminum-garnet (YAG) laser. ■

INDICATIONS:

- Diagnosis or ongoing monitoring of glaucoma
- Screening test included in a routine eye examination

RESULT

Normal Findings:

- Normal intraocular pressure is between 13 and 22 mm Hg.

Abnormal Findings:

- Open-angle glaucoma
- Primary angle closure glaucoma
- Secondary glaucoma

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Inability of the patient to remain still and cooperative during the test may interfere with the test results.

Nursing Implications and Procedure

Pretest:

➤ Inform the patient that the procedure measures the intraocular pressure of the eye.

- Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to topical anesthetic eyedrops.
- Obtain a history of the patient's known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- Obtain a history of results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Explain that the patient will be requested to fixate the eyes during the procedure. Address concerns about pain related to the procedure. Explain to the patient that he or she may feel coldness or a slight sting when the anesthetic drops are instilled at the beginning of the procedure, but that no discomfort will be experienced during the test. Instruct the patient as to what should be expected with the use of the tonometer. The patient will experience less anxiety if he or she understands that the tonometer tip will touch the tear film and not the eye directly. Inform the patient that a technician, optometrist, or physician performs the test, in a quiet, darkened room, and that to evaluate both eyes, the test can take 1 to 3 minutes.
- Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because any movement, such as coughing, breath holding, or wandering eye movements, produces unreliable results.
- Seat the patient comfortably. Instruct the patient to look at directed target while the eyes are examined.
- Instill ordered topical anesthetic in each eye, as ordered, and allow time for it to work. Topical anesthetic drops are placed in the eye with the patient looking up and the solution directed at the six o'clock position of the sclera (white of the eye) near the limbus (grey, semitransparent area of the eyeball where the cornea and sclera meet). The dropper bottle should not touch the eyelashes.
- Instruct the patient to look straight ahead, keeping the eyes open and unblinking.
- A number of techniques are used to measure intraocular pres-sure. Intraocular pressure can be measured at the slit lamp or with a miniaturized, handheld applanation tonometer or an airpuff tonometer.
- When the applanation tonometer is positioned on the patient's cornea, place the instrument's headrest against the patient's forehead. The tonometer should be held at an angle with the handle slanted away from the patient's nose. The tonometer tip should not touch the eyelids.
- When the tip is properly aligned and in contact with the fluorescein-stained tear film, force is applied to the tip using an adjustment control to the desired endpoint. The tonometer is removed from the eye. The reading is taken a second time and, if the pressure is elevated, a third reading is taken. The procedure is repeated on the other eye.
- With the airpuff tonometer, an air

pump blows air onto the cornea, and the time it takes for the air puff to flatten the cornea is detected by infrared light and photoelectric cells. This time is directly related to the intraocular pressure.

- The results are recorded manually, taking care to denote left and right readings, for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss or perceived loss of driving privileges. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications, usually eyedrops, that are intended to decrease intraocular pressure. Explain the importance of adhering to the therapy regimen, especially since increased intraocular pressure does not present symptoms. Instruct the patient in both the ocular side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include fundus photography, gonioscopy, nerve fiber analysis, slit-lamp biomicroscopy, and visual field testing.

INTRAVENOUS PYELOGRAPHY

SYNONYMS/ACRONYMS: Excretory urography (EUG), intravenous urography (IVU, IUG), IVP.

AREA OF APPLICATION: Kidneys, ureters, bladder, and renal pelvis.

CONTRAST: Intravenous radiopaque iodine-based contrast medium.

DESCRIPTION & RATIONALE: Intravenous pyelography (IVP) is the most commonly performed test to determine urinary tract dysfunction or renal disease. IVP uses IV radiopaque contrast medium to visualize the kidneys, ureters, bladder, and renal pelvis. The contrast medium concentrates in the blood and is filtered out by the glomeruli; it passes out through the renal tubules and is concentrated in the urine. Renal function is reflected by the length of time it takes the contrast medium to appear and to be excreted by each kidney. A series of x-rays is performed during a 30-minute period to view passage of the medium through the kidneys and ureters into the bladder. A final film is taken after the patient empties the bladder (postvoiding film). Computed tomography may be employed during the examination to permit the examination of an individual layer or plane of the organ that may be obscured by surrounding overlying structures. ■

INDICATIONS:

- Aid in the diagnosis of renovascular hypertension
- Evaluate the cause of blood in the urine
- Evaluate the effects of urinary system trauma
- Evaluate function of the kidneys, ureters, and bladder
- Evaluate known or suspected ureteral obstruction
- Evaluate the presence of renal, ureter, or bladder calculi
- Evaluate space-occupying lesions or congenital anomalies of the urinary system

RESULT

Normal Findings:

- Normal size and shape of kidneys, ureters, and bladder
- Normal bladder and absence of masses or renal calculi, with prompt visualization of contrast medium through the urinary system

Abnormal Findings:

- Absence of a kidney (congenital malformation)
- Benign and malignant kidney tumors
- Bladder tumors
- Congenital renal or urinary tract abnormalities
- Glomerulonephritis
- Hydronephrosis
- Prostatic enlargement
- Pyelonephritis
- Renal cysts
- Renal hematomas
- Renal or ureteral calculi
- Soft-tissue masses
- Tumors of the collecting system

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients with bleeding disorders.

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.
- Patients with renal insufficiency, indicated by a blood urea nitrogen value greater than 40 mg/dL, because contrast medium can complicate kidney function.
- Young patients (17 years old and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.
- Patients with multiple myeloma, who may experience decreased kidney function subsequent to administration of contrast medium.

Factors that may impair clear imaging:

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- End-stage renal disease, which may produce an examination of poor quality

Other considerations:

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the kidneys, ureters, and bladder.
- Obtain a history of the patient's complaints or symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, and dyes.
- Obtain a history of the patient's gastrointestinal and genitourinary systems, and results of previously performed diagnostic procedures,

surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Gastrointestinal and Genitourinary System tables.

- Ensure that this procedure is performed before an upper gastrointestinal study or barium swallow.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Explain the purpose of the test and how the procedure is performed. Inform the patient that the procedure is performed in a radiology department, usually by a technologist and support staff, and takes approximately 30 to 60 minutes.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to fast and restrict fluids for 8 hours prior to the procedure.
- Patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hours after the test. Failure to do so may result in lactic acidosis.
- Instruct the patient to take a laxative or a cathartic, as ordered, on the evening before the examination.
- Instruct the patient to remove jewelry (including watches), credit cards, and other metallic objects.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that the patient has complied with dietary and medication restrictions and pretesting preparations for at least 8 hours prior to the procedure. Ensure that the patient has removed all external metallic objects prior to the procedure.
- Assess for completion of bowel preparation according to the institution's procedure. Administer enemas or suppositories on the morning of the test, as ordered.
- Have emergency equipment readily available.
- Patients are given a gown and robe to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table.
- For male patients, place lead protection over the testicles to prevent their irradiation but remove it for bladder exposures.
- A kidney, ureter, and bladder (KUB) or plain film is taken to ensure that no barium or stool obscures visualization of the urinary system.
- Insert an IV line, if one is not already in place, and inject the contrast medium.
- X-ray exposures are made at 1, 5, 10, 15, 20, and 30 minutes to follow the course of the contrast medium through the urinary system. Instruct the patient to exhale deeply and to hold his or her breath while the x-ray is taken, and then to breathe after the film is taken.
- Ask the patient to void; a postvoiding exposure is done to visualize the empty bladder.

- The results are recorded manually, on film, or by automated equipment in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the health care practitioner.
- Monitor for reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Monitor urinary output after the procedure. Decreased urine output may indicate impending renal failure.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the abdomen, magnetic resonance imaging of the abdomen, renogram, and ultrasound of the kidney.

INTRINSIC FACTOR ANTIBODIES

SYNONYM/ACRONYM: IF antibodies.

SPECIMEN: Serum (1 mL) collected in a red-top tube. Plasma (1 mL) collected in a lavender-top (EDTA) tube is also acceptable.

REFERENCE VALUE: (Method: Radioimmunoassay) None detected.

DESCRIPTION & RATIONALE: Intrinsic factor (IF) is produced by the parietal cells of the gastric mucosa and is required for the normal absorption of vitamin B_{12}. In some diseases, antibodies are produced that bind the cobalamin-IF complex, prevent the complex from binding to ileum receptors, and prevent vitamin B_{12} absorption. There are two types of antibodies: type 1, the more commonly present blocking antibody; and type 2, the binding antibody. The blocking antibody inhibits uptake of vitamin B_{12} at the binding site of IF. Binding antibody combines with either free or complexed IF. ■

INDICATIONS:

- Assist in the diagnosis of pernicious anemia
- Evaluate patients with decreased vitamin B_{12} levels

RESULT

Increased in:

- Megaloblastic anemia
- Pernicious anemia
- Some patients with hyperthyroidism
- Some patients with insulin-dependent (type 1) diabetes

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Recent treatment with methotrexate or another folic acid antagonist can interfere with test results.
- Vitamin B_{12} injected or ingested within 48 hours of the test invalidates results.
- Recent radioactive scans or radiation can interfere with test results when radioimmunoassay is the test method.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the investigation of suspected pernicious anemia.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic and gastrointestinal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic and Gastrointestinal System tables.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient is regularly using these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food or fluid restrictions, unless by medical direction.

Administration of vitamin B_{12} should be withheld within 48 hours before testing.

Intratest:

- Ensure that vitamin B_{12} has been withheld within 48 hours before testing.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include complete blood count, folic acid, red blood cell indices, and vitamin B_{12}.

IRON

SYNONYM/ACRONYM: Fe.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 0.179)
Newborn	100–250 μg/dL	17.9–44.8 μmol/L
Infant–9 y	20–105 μg/dL	3.6–18.8 μmol/L
10–14 y	20–145 μg/dL	3.6–26.0 μmol/L
Adult		
Male	65–175 μg/dL	11.6–31.3 μmol/L
Female	50–170 μg/dL	9–30.4 μmol/L

DESCRIPTION & RATIONALE: Iron plays a principal role in erythropoiesis. Iron is necessary for the proliferation and maturation of red blood cells and is required for hemoglobin synthesis. Of the body's normal 4 g of iron, approximately 65% resides in hemoglobin and 3% in myoglobin. A small amount is also found in cellular enzymes that catalyze the oxidation and reduction of iron. The remainder of iron is stored in the liver, bone marrow, and spleen as ferritin or hemosiderin. Any iron present in the serum is in transit among the alimentary tract, the bone marrow, and available iron storage forms. Iron travels in the bloodstream bound to transferrin, a protein manufactured by the liver. Normally, iron enters the body by oral ingestion; only 10% is absorbed, but up to 20% can be absorbed in patients with iron-deficiency anemia. Unbound iron is highly toxic, but there is generally an excess of transferrin available to prevent the buildup of unbound iron in the circulation. Iron overload is as clinically significant as iron deficiency, especially in the accidental poisoning of children caused by excessive intake of iron-containing multivitamins. ■

INDICATIONS:

- Assist in the diagnosis of blood loss, as evidenced by decreased serum iron
- Assist in the diagnosis of hemochromatosis or other disorders of iron metabolism and storage
- Determine the differential diagnosis of anemia
- Determine the presence of disorders that involve diminished protein synthesis or defects in iron absorption
- Evaluate accidental iron poisoning
- Evaluate iron overload in dialysis patients or patients with transfusion-dependent anemias
- Evaluate thalassemia and sideroblastic anemia
- Monitor hematologic responses during pregnancy, when serum iron is usually decreased
- Monitor response to treatment for anemia

RESULT

Increased in:

- Acute iron poisoning (children)
- Acute leukemia
- Acute liver disease
- Aplastic anemia
- Excessive iron therapy
- Hemochromatosis
- Hemolytic anemias
- Lead toxicity
- Nephritis

- Pernicious anemias
- Sideroblastic anemias
- Thalassemia
- Transfusions (repeated)
- Vitamin B_6 deficiency

Decreased in:

- Acute and chronic infection
- Carcinoma
- Chronic blood loss (gastrointestinal, uterine)
- Hypothyroidism
- Iron-deficiency anemia
- Nephrosis
- Postoperative state
- Protein malnutrition (kwashiorkor)
- Remission of pernicious anemia

CRITICAL VALUES:

Mild toxicity: greater than 350 µg/dL

Serious toxicity: greater than 400 µg/dL

Lethal: greater than 1000 µg/dL

Note and immediately report to the health care practitioner any critically increased values and related symptoms. Intervention may include chelation therapy by administration of deferoxamine mesylate (Desferal).

INTERFERING FACTORS:

- Drugs that may increase iron levels include blood transfusions, chemotherapy drugs, iron (intramuscular), iron dextran, iron-protein-succinylate, methimazole, methotrexate, oral contraceptives, and rifampin.
- Drugs that may decrease iron levels include acetylsalicylic acid, allopurinol, cholestyramine, corticotropin, cortisone, deferoxamine, and metformin.
- Gross hemolysis can interfere with test results.
- Failure to withhold iron-containing medications 24 hours before the test may falsely increase values.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used in the differential diagnosis of anemia.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal and hematopoietic systems and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Gastrointestinal and Hematopoietic System tables.
- Note any recent therapies that can interfere with test results. Specimen collection should be delayed for several days after blood transfusion.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.

- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to fast for at least 12 hours before testing, and with medical direction, to refrain from taking iron-containing medicines before specimen collection.
- There are no fluid restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with dietary and medication restrictions; assure that food has been restricted for at least 12 hours prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the health care practitioner.
- *Nutritional considerations:* Educate the patient with abnormally elevated iron values, as appropriate, on the importance of reading food labels. Foods high in iron include meats (especially liver), eggs, grains, and green leafy vegetables. It is also important to explain that iron levels in foods can be increased if foods are cooked in cookware containing iron.
- *Nutritional considerations:* Educate the patient with abnormal iron values that numerous factors affect the absorption of iron, enhancing or decreasing absorption regardless of the original content of the iron-containing dietary source. Consumption of large amounts of alcohol damages the intestine and allows increased absorption of iron. A high intake of calcium and ascorbic acid also increases iron absorption. Iron absorption after a meal is also increased by factors in meat, fish, or poultry. Iron absorption is decreased by the absence (gastric resection) or diminished presence (use of antacids) of gastric acid. Phytic acids from cereals, tannins from tea and coffee, oxalic acid from vegetables, and minerals such as copper, zinc, and manganese interfere with iron absorption.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

Related laboratory tests include bone marrow biopsy, liver biopsy, complete blood count, erythropoietin, ferritin, hemosiderin, iron/total iron-binding capacity, lead, porphyrins, and transferrin.

IRON-BINDING CAPACITY (TOTAL), TRANSFERRIN, AND IRON SATURATION

SYNONYMS/ACRONYMS: TIBC, Fe Sat.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Spectrophotometry for TIBC and nephelometry for transferrin)

Test	Conventional Units	SI Units
		(Conventional Units × 0.179)
TIBC	250–350 μg/dL	45–63 μmol/L
		(Conventional Units × 0.01)
Transferrin	200–380 mg/dL	2–3.8 g/L
Iron saturation	20–50%	

TIBC = total iron-binding capacity.

DESCRIPTION & RATIONALE: Iron plays a principal role in erythropoiesis. It is necessary for proliferation and maturation of red blood cells and for hemoglobin synthesis. Of the body's normal 4 g of iron (less in women), about 65% is present in hemoglobin and about 3% in myoglobin. A small amount is also found in cellular enzymes that catalyze the oxidation and reduction of iron. The remainder of iron is stored in the liver, bone marrow, and spleen as ferritin or hemosiderin. Any iron present in the

serum is in transit among the alimentary tract, the bone marrow, and available iron storage forms. Iron travels in the bloodstream bound to transport proteins. Transferrin is the major iron-transport protein, carrying 60% to 70% of the body's iron. For this reason, total iron-binding capacity (TIBC) and transferrin are sometimes referred to interchangeably, even though other proteins carry iron and contribute to the TIBC. Unbound iron is highly toxic, but there is generally an excess of transferrin available to prevent the buildup of unbound iron in the circulation. The percentage of iron saturation is calculated by dividing the serum iron value by the TIBC value and multiplying by 100. ■

INDICATIONS:

- Assist in the diagnosis of iron-deficiency anemia
- Differentiate between iron-deficiency anemia and anemia secondary to chronic disease
- Monitor hematologic response to therapy during pregnancy and iron-deficiency anemias
- Provide support for diagnosis of hemochromatosis or diseases of iron metabolism and storage

RESULT

Increased in:

- Acute liver disease
- Hypochromic (iron-deficiency) anemias
- Late pregnancy

Decreased in:

- Chronic infections
- Cirrhosis
- Hemochromatosis
- Hemolytic anemias
- Neoplastic diseases
- Protein depletion
- Renal disease
- Sideroblastic anemias
- Thalassemia

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase TIBC levels include mestranol and oral contraceptives.
- Drugs that may decrease TIBC levels include asparaginase, chloramphenicol, corticotropin, cortisone, and testosterone.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used in the differential diagnosis of anemia.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex) and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic System table.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient is regularly using these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns

about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.

- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include bone marrow biopsy, complete blood count, erythropoietin, ferritin, hemosiderin, iron, lead, and porphyrins.

KETONES, BLOOD AND URINE

SYNONYMS/ACRONYM: Ketone bodies, acetoacetate, acetone.

SPECIMEN: Serum (1 mL) collected from red- or tiger-top tube. Urine (5 mL), random or timed specimen, collected in a clean plastic collection container.

REFERENCE VALUE: (Method: Colorimetric nitroprusside reaction) Negative.

DESCRIPTION & RATIONALE: Ketone bodies refer to the three intermediate products of metabolism: acetone, acetoacetic acid, and β-hydroxybutyrate. Even though β-hydroxybutyrate is not a ketone, it is usually listed with the ketone bodies. In healthy individuals, ketones are produced and completely metabolized by the liver so that measurable amounts are not normally present in serum. Ketones appear in the urine before a significant serum level is detectable. If the patient has excessive fat metabolism, ketones are found in blood and urine. Excessive fat metabolism may occur if the patient has impaired ability to metabolize carbohydrates, inadequate carbohydrate intake, inadequate insulin levels, excessive carbohydrate loss, or increased carbohydrate demand. A strongly positive acetone result without severe acidosis, accompanied by normal glucose, electrolyte, and bicarbonate levels, is strongly suggestive of isopropyl alcohol poisoning. A low-carbohydrate or low-fat diet may cause a positive acetone test. Ketosis in diabetics is usually accompanied by increased glucose and decreased bicarbonate and pH. Extremely elevated levels of ketone bodies can result in coma. This situation is particularly life-threatening in children younger than 10 years old. ■

INDICATIONS:

- Assist in the diagnosis of starvation, stress, alcoholism, suspected isopropyl alcohol ingestion, glycogen storage disease, and other metabolic disorders
- Detect and monitor treatment of diabetic ketoacidosis
- Monitor the control of diabetes
- Screen for ketonuria due to acute illness or stress in nondiabetic patients
- Screen for ketonuria to assist in the assessment of inborn errors of metabolism
- Screen for ketonuria to assist in the diagnosis of suspected isopropyl alcohol poisoning

RESULT

Increased in:

- Acidosis
- Branched-chain ketonuria
- Carbohydrate deficiency
- Eclampsia
- Fasting or starvation
- Gestational diabetes
- Glycogen storage diseases
- High-fat or high-protein diet
- Hyperglycemia
- Ketoacidosis of alcoholism and diabetes
- Illnesses with marked vomiting and diarrhea
- Isopropyl alcohol ingestion
- Methylmalonic aciduria
- Postanesthesia period
- Propionyl coenzyme A carboxylase deficiency

Decreased in: N/A

CRITICAL VALUES:

Strongly positive test results for glucose and ketones

Note and immediately report to the health care practitioner strongly positive results in urine and related symptoms. An elevated level of ketone bodies is evidenced by fruity-smelling breath, acidosis, ketonuria, and decreased level of

consciousness. Administration of insulin and frequent blood glucose measurement may be indicated.

INTERFERING FACTORS:

- Drugs that may cause an increase in serum ketone levels include acetylsalicylic acid (if therapy results in acidosis, especially in children), albuterol, fenfluramine, levodopa, nifedipine, and paraldehyde.
- Drugs that may cause a decrease in serum ketone levels include acetylsalicylic acid and valproic acid. Increases have been shown in hyperthyroid patients receiving propranolol and propylthiouracil.
- Drugs that may increase urine ketone levels include acetylsalicylic acid (if therapy results in acidosis, especially in children), captopril, dimercaprol, ether, ifosfamide, insulin, levodopa, mesna, metformin, methyldopa, *N*-acetylcysteine, niacin, paraldehyde, penicillamine, phenazopyridine, phenolphthalein, phenolsulfonphthalein, pyrazinamide, streptozocin, sulfobromophthalein, and valproic acid.
- Drugs that may decrease urine ketone levels include acetylsalicylic acid and phenazopyridine.
- Urine should be checked within 60 minutes of collection.
- Bacterial contamination of urine can cause false-negative results.
- Failure to keep reagent strip container tightly closed can cause false-negative results. Light and moisture affect the ability of the chemicals in the strip to perform as expected.
- False-negative or weakly false-positive test results can be obtained when β-hydroxybutyrate is the predominating ketone body in cases of lactic acidosis.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is most commonly used to investigate diabetes as the cause of ketoacidosis.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine System table.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that blood specimen collection takes approximately 5 to 10 minutes. The amount of time required to collect a urine specimen depends on the level of cooperation from the patient. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Observe standard precautions, and follow the general guidelines in Appendix A.

Blood:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube. Alternatively, a finger- or heelstick method of specimen collection can be used.
- Remove the needle, and apply a pressure dressing over the puncture site.

Urine:

- Review the procedure with the patient. Explain to the patient how to collect a second-voided midstream specimen: (1) void, then drink a glass of water; and (2) wait 30 minutes, and then try to void again.
- Instruct the patient to avoid excessive exercise and stress before specimen collection.

Clean-catch specimen:

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Blood or urine:

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Increased levels of ketone bodies may be associated with diabetes. The nutritional needs of each diabetic patient need to be determined individually (especially during pregnancy) by a health care practitioner trained in nutrition. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. There is no "diabetic diet"; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association.
- Impaired glucose tolerance may be associated with diabetes. Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).
- *Nutritional considerations:* Increased levels of ketone bodies may be associated with poor carbohydrate intake; therefore, the body breaks down fat instead of carbohydrate for energy. Increasing carbohydrate intake in the patient's diet reduces the levels of ketone bodies. Carbohydrates can be found in starches and sugars. Starch is a complex carbohydrate that can be found in foods such as grains (breads, cereals, pasta, rice) and

starchy vegetables (corn, peas, potatoes). Sugar is a simple carbohydrate that can be found in natural foods (fruits and natural honey) and processed foods (desserts and candy).

- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, as appropriate, that good glycemic control delays the onset of and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Diabetes Association *(http://www.diabetes.org)*.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include anion gap, blood gases, electrolytes, glucose, glycated hemoglobin, lactic acid, osmolality (blood and urine), phosphorus, and routine urinalysis.

KIDNEY, URETER, AND BLADDER STUDY

SYNONYMS/ACRONYM: Flat plate of the abdomen, plain film of the abdomen, scout film, KUB.

AREA OF APPLICATION: Kidneys, ureters, bladder, and abdomen.

CONTRAST: None.

DESCRIPTION & RATIONALE: A kidney, ureter, and bladder (KUB) x-ray examination provides information regarding the structure, size, and position of the abdominal organs; it also indicates whether there is any obstruction or abnormality of the abdomen caused by disease or congenital mal-

formation. Calcifications of the renal calyces or renal pelvis, as well as any radiopaque calculi present in the urinary tract or surrounding organs, may be visualized. Patterns of air and gas appear light and bright on the image. Air normally remains contained within the intestinal tract; perforation of either the stomach or the intestines causes air to escape into the abdominal cavity. When there is an intestinal obstruction, air and fluid collect above the area of obstruction, distending the lumen of the intestine. KUB x-rays are among the first examinations done to diagnose intra-abdominal diseases such as intestinal obstruction, masses, tumors, ruptured organs, abnormal gas accumulation, and ascites. ■

INDICATIONS:

- Determine the cause of acute abdominal pain or palpable mass
- Evaluate the effects of lower abdominal trauma, such as internal hemorrhage
- Evaluate known or suspected intestinal obstruction
- Evaluate the presence of renal, ureter, or other organ calculi
- Evaluate the size, shape, and position of the liver, kidneys, and spleen
- Evaluate suspected abnormal fluid, air, or metallic object or obstruction in the abdomen

RESULT

Normal Findings:

- Normal size and shape of kidneys
- Normal bladder, absence of masses and renal calculi, and no abnormal accumulation of air or fluid

Abnormal Findings:

- Abnormal accumulation of bowel gas
- Ascites
- Bladder distention
- Congenital renal anomaly
- Hydronephrosis
- Intestinal obstruction
- Organomegaly
- Renal calculi
- Renal hematomas
- Ruptured viscus
- Soft-tissue masses
- Trauma to liver, spleen, kidneys, and bladder
- Vascular calcification

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined, especially

for oblique and decubitus views and for films done by portable equipment

- Retained barium from a previous radiologic procedure
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Ascites, uterine tumors, and ovarian tumors, which can interfere with the quality of the procedure

Other considerations:

- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the status of the abdomen.
- Obtain a history of the patient's complaints and symptoms.
- Obtain a history of the patient's gastrointestinal and genitourinary systems, and results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Gastrointestinal and Genitourinary System tables.
- Schedule intravenous pyelography (IVP) or gastrointestinal studies after this study.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that little or no pain is expected during the test, but there may be moments of discomfort. Inform the patient that the procedure is performed in the radiology department or at the bedside, by a registered radiologic techologist, and takes approximately 5 to 15 minutes to complete.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication, restrictions unless by medical direction.
- Instruct the patient to remove jewelry (including watches), credit cards, and other metallic objects.

Intratest:

- Ensure that jewelry, watches, chains, belts, and any other metallic objects have been removed from the abdominal area.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Remove any wires connected to electrodes, if allowed.
- Place the patient on the table in a supine position with hands over the head or relaxed at the side.
- For male patients, place lead protection over the testicles to prevent their irradiation.

- For portable examinations, elevate the head of the bed to the high Fowler's position.
- Ask the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- The results are recorded on a sheet of x-ray film or electronically, in a computerized system, for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include IVP as well as computed tomography, ultrasound, and magnetic resonance imaging of the abdomen.

KLEIHAUER-BETKE TEST

SYNONYMS/ACRONYM: Fetal hemoglobin, hemoglobin F, acid elution slide test.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube. Freshly prepared blood smears are also acceptable. Cord blood may be requested for use as a positive control.

REFERENCE VALUE: (Method: Microscopic examination of treated and stained peripheral blood smear) Less than 1%.

DESCRIPTION & RATIONALE: The Kleihauer-Betke test is used to determine the degree of fetal-maternal hemorrhage and to help calculate the dosage of RhoGAM to be given in some cases of Rh-negative mothers. The test can also be used to distinguish some forms of thalassemia from the hereditary persistence of fetal hemoglobin, but hemoglobin electrophoresis and flow cytometry methods are more commonly used for this purpose. ■

INDICATIONS:

- Assist in the diagnosis of certain types of anemia
- Calculating dosage of RhoGAM
- Screening postpartum maternal blood for the presence of fetal-maternal hemorrhage

RESULT

Positive in:

- Fetal-maternal hemorrhage
- Hereditary persistence of fetal hemoglobin

Negative in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS: Specimens must be obtained before transfusion.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to determine occurrence and extent of fetal-maternal bleed. It is also used to calculate Rh immune globulin dosage.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic and reproductive systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic and Reproductive System tables.
- Note any recent procedures that can interfere with test results.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL lavender-top tube.
- Remove the needle and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis. Sample must be less than 6 hours old.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to

hold pressure bandage in place, or replace with a plastic bandage.

- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include blood group and type and hemoglobin electrophoresis.

LACTATE DEHYDROGENASE AND ISOENZYMES

SYNONYMS/ACRONYMS: LDH and isos, LD and isos.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Enzymatic [L to P] for lactate dehydrogenase, electrophoretic analysis for isoenzymes) Reference ranges are method dependent and may vary from laboratory to laboratory.

Lactate Dehydrogenase

Age	Conventional & SI Units
0–2 y	125–275 U/L
2–3 y	166–232 U/L
4–6 y	104–206 U/L
7–12 y	90–203 U/L
13–14 y	90–199 U/L
15–43 y	90–156 U/L
Greater than 43 y	90–176 U/L

LDH Fraction	% of Total	Fraction of Total
LDH_1	14–26	0.14–0.26
LDH_2	29–39	0.29–0.39
LDH_3	20–26	0.20–0.26
LDH_4	8–16	0.08–0.16
LDH_5	6–16	0.06–0.16

DESCRIPTION & RATIONALE: Lactate dehydrogenase (LDH) is an enzyme that catalyzes the reversible conversion of lactate to pyruvate within cells. Because many tissues contain LDH, elevated total LDH is considered a nonspecific indicator of cellular damage unless other clinical data make the tissue origin obvious. Determining tissue origin is aided by electrophoretic analysis of the five isoenzymes specific to certain tissues. The heart and erythrocytes are rich sources of LDH_1, LDH_2, and LDH_3; the kidneys contain large amounts of LDH_3 and LDH_4; and the liver and skeletal muscles are high in LDH_4 and LDH_5. Certain glands (e.g., thyroid, adrenal, thymus), the pancreas, spleen, lungs, lymph nodes, and white blood cells contain LDH_3, whereas the ilium is an additional source of LDH_5. There have been documented reports of a sixth isoenzyme of LDH. It is seen in patients with severe liver disease and is an indicator of a very poor prognosis. LDH is found in every tissue of the body. It is of no use as a specific diagnostic marker. Testing for the presence of LDH and isoenzymes is rarely used anymore to confirm acute myocardial infarction (MI), having been replaced by more sensitive and specific creatine kinase (CK-MB) and troponin assays. Acute myocardial infarction releases LDH into the serum within the first 12 hours, causing a "flip" isoenzyme pattern within 48 hours of MI, and levels remain elevated 1 to 2 weeks after CK and aspartate aminotransferase have returned to normal levels. ■

INDICATIONS:

- Differentiate acute MI, as evidenced by elevated LDH_1 and LDH_2, from pulmonary infarction and liver problems, which elevate LDH_4 and LDH_5
- Evaluate the degree of muscle wasting in muscular dystrophy (LDH levels rise early in this disorder and approach normal as muscle mass is reduced by atrophy)
- Evaluate the effectiveness of cancer chemotherapy (LDH levels should fall with successful treatment)
- Evaluate red cell hemolysis or renal infarction, especially as indicated by reversal of the LDH_1:LDH_2 ratio
- Investigate acute MI or extension thereof, as indicated by elevation (usually) of total LDH, elevation of LDH_1 and LDH_2, and reversal of the LDH_1:LDH_2 ratio within 48 hours of the infarction
- Investigate chronicity of liver, lung, and kidney disorders, as evidenced by LDH levels that remain persistently high

RESULT

Total LDH increased in:

- Carcinoma of the liver
- Chronic alcoholism

- Cirrhosis
- Congestive heart failure
- Hemolytic anemias
- Hypoxia
- Leukemias
- Megaloblastic and pernicious anemia
- MI or pulmonary infarction
- Musculoskeletal disease
- Obstructive jaundice
- Pancreatitis
- Renal disease (severe)
- Shock
- Viral hepatitis

Total LDH decreased in: N/A

LDH Isoenzymes:

- LDH_1 fraction increased over LDH_2 can be seen in acute MI, anemias (pernicious, hemolytic, acute sickle cell, megaloblastic, hemolytic), and acute renal cortical injury due to any cause. The LDH_1 fraction in particular is elevated in cases of germ cell tumors.
- Increases in the middle fractions are associated with conditions in which massive platelet destruction has occurred (e.g., pulmonary embolism, post-transfusion period), and in lymphatic system disorders (e.g., infectious mononucleosis, lymphomas, lymphocytic leukemias).
- An increase in LDH_5 occurs with musculoskeletal damage and many types of liver damage (e.g., cirrhosis, cancer, hepatitis).

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase total LDH levels include amiodarone, etretinate, fluosol-DA, methotrexate, oxacillin, plicamycin, propoxyphene, and streptokinase.
- Drugs that may decrease total LDH levels include ascorbic acid, cefotaxime, enalapril, fluorides, naltrexone, and oxylate.
- Hemolysis will cause significant false elevations in total LDH and a false "flip" pattern of the isoenzymes because LDH_1 fraction is of red blood cell origin.
- Some isoenzymes are temperature sensitive; therefore, prolonged storage at refrigerated temperatures may cause false decreases.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to monitor MI.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular, hematopoietic, hepatobiliary, and musculoskeletal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Cardiovascular, Hematopoietic, Hepatobiliary, and Musculoskeletal System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the

patient. (Samples at time of admission, 2 to 4 hours, 6 to 8 hours, and 12 hours after admission are the minimal recommendations. Additional samples may be requested.) Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.

- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Increased LDH levels may be associated with coronary artery disease (CAD). Nutritional therapy is recommended for individuals identified to be at high risk for developing CAD. If overweight, the patient should be encouraged to achieve a normal weight. The American Heart Association Step 1 and Step 2 diets may be helpful in achieving a goal of lowering total cholesterol and triglyceride levels. The Step 1 diet emphasizes a reduction in foods high in saturated fats and cholesterol. Red meats, eggs, and dairy products are the major sources of saturated fats and cholesterol. If triglycerides are also elevated, the patient should be advised to eliminate or reduce alcohol and simple carbohydrates from the diet. The Step 2 diet recommends stricter reductions.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association *(http://www.americanheart.org)*.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

Related laboratory tests include antiarrhythmic drugs, apolipoprotein A, apolipoprotein B, aspartate aminotransferase, atrial natriuretic peptide, blood gases, B-type natriuretic peptide, calcium (blood and ionized), cholesterol (total, HDL, and LDL), C-reactive protein, creatine kinase and isoenzymes, γ-glutamyltranspeptidase, glucose, glycated hemoglobin, homocysteine, ketones, pleural fluid LDH, lipoprotein electrophoresis, magnesium, myoglobin, potassium, triglycerides, and troponin.

LACTIC ACID

SYNONYM/ACRONYM: Lactate.

SPECIMEN: Plasma (1 mL) collected in a gray-top (sodium fluoride) or green-top (lithium heparin) tube. Specimen should be transported tightly capped and in an ice slurry.

REFERENCE VALUE: (Method: Spectrophotometry/enzymatic analysis)

Conventional Units	SI Units (Conventional Units × 0.111)
3–23 mg/dL	0.3–2.6 mmol/L

DESCRIPTION & RATIONALE: Lactic acid (present in blood as lactate) is a byproduct of carbohydrate metabolism. Normally metabolized in the liver, lactate concentration is based on the rate of production and metabolism. Levels increase during strenuous exercise, which results in insufficient oxygen delivery to the tissues. Pyruvate, the normal end product of glucose metabolism, is converted to lactate in emergency situations when energy is needed but there is insufficient oxygen in the system to favor the aerobic and customary energy cycle. When hypoxia or circulatory collapse increases production of lactate, or when the hepatic system does not metabolize lactate sufficiently, lactate levels become elevated. The lactic acid test can be performed in conjunction with pyruvic acid testing to monitor tissue oxygenation. Lactic acidosis can be differentiated from ketoacidosis by the absence of ketosis and grossly elevated glucose levels. ■

INDICATIONS:

- Assess tissue oxygenation
- Evaluate acidosis

Result

Increased in:

- Cardiac failure
- Diabetes
- Hemorrhage
- Hepatic coma
- Ingestion of large doses of ethanol or acetaminophen
- Lactic acidosis
- Pulmonary embolism
- Pulmonary failure
- Reye's syndrome
- Shock
- Strenuous exercise

Decreased in: N/A

Critical Values:

Greater than or equal to 31 mg/dL

Note and immediately report to the health care practitioner any critically increased values and related symptoms. Observe the patient for signs and symptoms of elevated levels, such as Kussmaul's breathing and increased pulse rate. In general, there is an inverse relationship between critically elevated lactate levels and survival.

Interfering Factors:

- Drugs that may increase lactate levels include albuterol, anticonvulsants (long-term use), epinephrine, intravenous glucose, isoniazid, lactose, metformin, oral contraceptives, sodium bicarbonate, and sorbitol.
- Falsely low lactate levels are obtained in samples with elevated levels of the enzyme lactate dehydrogenase (LDH) because this enzyme reacts with the available lactate substrate.
- Using a tourniquet or instructing the patient to clench his or her fist during a venipuncture can cause elevated levels.
- Engaging in strenuous physical activity (i.e., activity in which blood flow and oxygen distribution cannot keep pace with increased energy needs) before specimen collection can cause an elevated result.
- Delay in transport of the specimen to the laboratory must be avoided. Specimens not processed by centrifugation in a tightly stoppered collection container within 15 minutes of collection should be rejected for analysis. It is preferable to transport specimens to the laboratory in an ice slurry to further retard cellular metabolism that might shift lactate levels in the sample before analysis.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to investigate suspected lactic acidosis, most commonly caused by hypoperfusion.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular, endocrine, hepatobiliary, musculoskeletal, and respiratory systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Cardiovascular, Endocrine, Hepatobiliary, Musculoskeletal, and Respiratory System tables.

- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Instruct the patient to rest for 1 hour before specimen collection. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- Instruct the patient to fast and to restrict fluids overnight. Instruct the patient not to ingest alcohol for 12 hours before the test.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no medication restrictions, unless by medical direction.
- Prepare an ice slurry in a cup or plastic bag to have on hand for immediate transport of the specimen to the laboratory.

Intratest:

- Ensure that the patient has complied with dietary restrictions and other pretesting preparations; assure that food and liquids have been restricted for at least 12 hours prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Instruct the patient *not* to clench and unclench fist immediately before or during specimen collection. Do not use a tourniquet. Perform a venipuncture; collect the specimen in a 5-mL gray- or green-top tube. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label can be protected from water in the ice slurry if the specimen is first placed in a protective plastic bag.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Instruct patients to consume water when exercising. Dehydration may occur when the body loses water during exercise. Early signs of dehydration include dry mouth, thirst, and concentrated dark yellow urine. If replacement fluids are not consumed at this time, the patient may become moderately dehydrated and exhibit symptoms of extreme thirst, dry oral mucus membranes, inability to produce tears, decreased urinary output, and light-headedness. Severe dehydration manifests as confusion, lethargy, vertigo, tachycardia, anuria, diaphoresis, and loss of consciousness.

- Instruct the patient to resume usual diet and fluids, as directed by the health care practitioner.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include anion gap, arterial/alveolar oxygen ratio, blood gases, electrolytes, glucose, and ketones.

LACTOSE TOLERANCE TEST

SYNONYM/ACRONYM: LTT.

SPECIMEN: Plasma (1 mL) collected in gray-top (fluoride/oxalate) tube.

REFERENCE VALUE: (Method: Spectrophotometry)

Change in Glucose Value	Conventional Units	SI Units (Conventional Units × 0.0555)
Normal*	Greater than 30 mg/dL	Greater than 1.7 mmol/L
Inconclusive*	20–30 mg/dL	1.1–1.7 mmol/L
Abnormal*	Less than 20 mg/dL	Less than 1.1 mmol/L

*Compared to fasting sample.

DESCRIPTION & RATIONALE: Lactose is a disaccharide found in dairy products. When ingested, lactose is broken down in the intestine, by the sugar-splitting enzyme lactase, into glucose and galactose. When sufficient lactase is not available, intestinal bacteria metabolize the lactose, resulting in abdominal bloating, pain, flatus, and diarrhea. The lactose tolerance test screens for lactose intolerance by monitoring glucose levels after ingestion of a dose of lactose. ■

INDICATIONS: Evaluate patients for suspected lactose intolerance

Result

Glucose levels increased in: N/A

Glucose levels decreased in:
Lactose intolerance

Critical Values:

Less than 40 mg/dL

Greater than 400 mg/dL

Note and immediately report to the health care practitioner any critically increased or decreased values and symptoms.

Symptoms of decreased glucose levels include headache, confusion, hunger, irritability, nervousness, restlessness, sweating, and weakness. Possible interventions include oral or intravenous (IV) administration of glucose, IV or intramuscular injection of glucagon, and continuous glucose monitoring.

Symptoms of elevated glucose levels include abdominal pain, fatigue, muscle cramps, nausea, vomiting, polyuria, and thirst. Possible interventions include subcutaneous or IV injection of insulin with continuous glucose monitoring.

Interfering Factors:

- Numerous medications may alter glucose levels (see monograph titled "Glucose").
- Delayed gastric emptying may decrease glucose levels.
- Smoking may falsely increase glucose levels.
- Failure to follow dietary and activity restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate lactose intolerance and other malabsorption disorders.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Gastrointestinal System table.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Obtain the pediatric patient's weight to calculate dose of lactose to be administered. Inform the patient that multiple samples will be collected over a 90-minute interval. Inform the patient that each specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Inform the patient that the test may produce symptoms such as cramps and diarrhea. Instruct the patient not to smoke cigarettes or chew gum during the test. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Inform the patient that fasting for at least 12 hours before the test is required and that strenuous activity should also be avoided for at least 12 hours before the test.
- There are no medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with dietary and activity restrictions as well as other pretesting preparations; assure that food has been restricted for at least 12 hours prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Administer 50 g of lactose dissolved in a small amount of water to adults over a 5- to 10-minute period. Pediatric dosage is based on weight: 0.6 to 1.3 g lactose per kilogram of body weight for infants less than 12 months old; 1.7 g lactose per kilogram of body weight for children 1 to 12 years old. Record time of ingestion. Encourage the patient to drink one to two glasses of water.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube or red pediatric Microtainer. Samples should be collected at baseline, 30, 45, 60, and 90 minutes. Record any symptoms the patient reports throughout the course of the test.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis. Glucose values change rapidly in an unprocessed, unpreserved specimen; therefore, if a Microtainer is used, each sample should be transported immediately after collection.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient that resuming his or her usual diet may not be possible if lactose intolerance is identified. Educate patients on the importance of following the dietary advice of a nutritionist to ensure proper nutritional balance.
- *Nutritional considerations:* Instruct the patient with lactose intolerance to avoid milk products and to carefully read labels on prepared products. Yogurt, which contains inactive lactase enzyme, may be ingested. The lactase in yogurt is activated by the temperature and pH of the duodenum and substitutes for the lack of endogenous lactase. Advise the patient that products such as Lactaid tablets or drops may allow ingestion of milk products without sequelae. Many lactose-free food products are now available in grocery stores.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of concerns related to a perceived change in lifestyle. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor

progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

Related laboratory tests include D-xylose absorption, fecal analysis, and glucose.

LAPAROSCOPY, ABDOMINAL

SYNONYM/ACRONYM: Abdominal peritoneoscopy.

AREA OF APPLICATION: Pelvis.

CONTRAST: Carbon dioxide (CO_2).

DESCRIPTION & RATIONALE: Abdominal or gastrointestinal laparoscopy provides direct visualization of the liver, gallbladder, spleen, and stomach after insufflation of carbon dioxide (CO_2). In this procedure, a rigid laparoscope is introduced into the body cavity through a 1- to 2-cm abdominal incision. The endoscope has a microscope to allow visualization of the organs, and it can be used to insert instruments for performing certain procedures, such as biopsy and tumor resection. Under general anesthesia, the peritoneal cavity is inflated with 2 to 3 L of CO_2. The gas distends the abdominal wall so that the instruments can be inserted safely. Advantages of this procedure compared to an open laparotomy include reduced pain, reduced length of stay at the hospital or surgical center, and reduced time off from work. ■

INDICATIONS:

- Assist in performing surgical procedures such as cholecystectomy, appendectomy, hernia repair, hiatal hernia repair, and bowel resection
- Detect cirrhosis of the liver
- Detect pancreatic disorders
- Evaluate abdominal pain or abdominal mass of unknown origin
- Evaluate abdominal trauma in an emergency
- Evaluate and treat appendicitis
- Evaluate the extent of splenomegaly due to portal hypertension
- Evaluate jaundice of unknown origin
- Obtain biopsy specimens of benign or cancerous tumors
- Stage neoplastic disorders such as lymphomas, Hodgkin's disease, and hepatic carcinoma

Result

Normal Findings:

- Normal appearance of the liver, spleen, gallbladder, pancreas, and other abdominal contents

Abnormal Findings:

- Abdominal adhesions
- Appendicitis
- Ascites
- Cancer of any of the organs
- Cirrhosis of the liver
- Gangrenous gallbladder
- Intra-abdominal bleeding
- Portal hypertension
- Splenomegaly

Critical Values: N/A

Interfering Factors:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risk of radiation exposure to the fetus
- Patients with bleeding disorders, especially those associated with uremia and cytotoxic chemotherapy
- Patients with cardiac conditions or dysrhythmias
- Patients with advanced respiratory or cardiovascular disease
- Patients with intestinal obstruction, abdominal mass, abdominal hernia, or suspected intra-abdominal hemorrhage
- Patients with a history of peritonitis or multiple abdominal operations causing dense adhesions

Factors that may impair clear visualization:

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Patients who are in a hypoxemic or hypercapnic state will require continuous oxygen administration.
- Patients with acute infection or advanced malignancy involving the abdominal wall are at increased risk because organisms may be introduced into the normally sterile peritoneal cavity.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the abdominal organs.
- Obtain a history of the patient's complaints, including a list of known

allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, and dyes. Assess if the patient has an allergy to local anesthetics, and inform the health care practitioner accordingly.

- Obtain a history of the patient's gastrointestinal, genitourinary, reproductive, and hepatobiliary systems, as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Gastrointestinal, Genitourinary, Reproductive, and Hepatobiliary System tables.
- Ensure that this procedure is performed before an upper gastrointestinal study or barium swallow.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Explain the purpose of the test and how the procedure is performed. Inform the patient that the procedure is performed in a surgery department, usually by a health care practitioner and support staff, and takes approximately 30 to 60 minutes.
- Explain that an intravenous (IV) line may be inserted to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to fast and restrict fluids for 8 hours prior to the procedure.
- Inform the patient that a laxative and cleansing enema may be needed the day before the procedure, with cleansing enemas on the morning of the procedure, depending on the institution's policy.
- Instruct the patient to remove jewelry (including watches), credit cards, and other metallic objects.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that the patient has complied with dietary and medication restrictions and pretesting preparations for at least 8 hours prior to the procedure. Ensure that the patient has removed all external metallic objects prior to the procedure.
- Ensure that nonallergy to anesthesia is confirmed before the procedure is performed under general anesthesia.
- Assess for completion of bowel preparation according to the institution's procedure.
- Have emergency equipment readily available.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Obtain and record baseline vital signs.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer medications, as ordered, to reduce discomfort and to promote relaxation and sedation.
- Insert an IV line or venous access device at a low "keep open" rate.
- Place the patient on the laparoscopy table. If general anesthesia is to be used, it is administered at this time. Then place the patient in a modified lithotomy position with the head tilted downward. Cleanse the

abdomen with an antiseptic solution, and drape and catheterize the patient, if ordered.

- The physician identifies the site for the scope insertion, and administers local anesthesia if that is to be used. After deeper layers are anesthetized, a pneumoperitoneum needle is placed between the visceral and parietal peritoneum.
- CO_2 is insufflated through the pneumoperitoneum needle to separate the abdominal wall from the viscera and to aid in visualization of the abdominal structures. The pneumoperitoneum needle is removed, and the trocar and laparoscope are inserted through the incision.
- After the examination, collection of tissue samples, and performance of therapeutic procedures, the scope is withdrawn. All possible CO_2 is evacuated via the trocar, which is then removed. The skin incision is closed with sutures, clips, or sterile strips, and a small dressing or adhesive strip is applied.

Post-test:

- Monitor vital signs and neurologic status every 15 minutes for 1 hour, then every 2 hours for 4 hours, and as ordered. Take temperature every 4 hours for 24 hours. Compare with baseline values. Notify the health care practitioner if temperature is elevated. Protocols may vary from facility to facility.
- Instruct the patient to resume usual diet, fluids, and medication, as directed by the health care practitioner.
- Instruct the patient to restrict activity for 2 to 7 days after the procedure.
- If indicated, inform the patient of a follow-up appointment for the removal of sutures.
- Inform the patient that shoulder discomfort may be experienced for 1 or 2 days after the procedure as a result of abdominal distention caused by insufflation of CO_2 into the abdomen, and that mild analgesics and cold compresses, as ordered, can be used to relieve the discomfort.
- Emphasize that any persistent shoulder pain, abdominal pain, vaginal bleeding, fever, redness, or swelling of the incisional area must be reported to the health care practitioner immediately.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the abdomen; hepatobiliary scan; kidney, ureter, and bladder study; magnetic resonance imaging of the abdomen; and ultrasound of the abdomen.

LAPAROSCOPY, GYNECOLOGIC

SYNONYMS/ACRONYM: Gynecologic pelviscopy, gynecologic laparoscopy, pelvic endoscopy, peritoneoscopy.

AREA OF APPLICATION: Pelvis.

CONTRAST: Carbon dioxide (CO_2).

DESCRIPTION & RATIONALE: Gynecologic laparoscopy provides direct visualization of the internal pelvic contents, including the ovaries, fallopian tubes, and uterus, after insufflation of carbon dioxide (CO_2). It is done to diagnose and treat pelvic organ disorders, as well as to perform surgical procedures on the organs. In this procedure, a rigid laparoscope is introduced into the body cavity through a 1- to 2-cm periumbilical incision. The endoscope has a microscope to allow visualization of the organs, and it can be used to insert instruments for performing certain procedures, such as biopsy and tumor resection. Under general or local anesthesia, the peritoneal cavity is inflated with 2 to 3 L of CO_2. The gas distends the abdominal wall so that the instruments can be inserted safely. Advantages of this procedure compared to an open laparotomy include reduced pain, reduced length of stay at the hospital or surgical center, and reduced time off from work. ■

INDICATIONS:

- Detect ectopic pregnancy and determine the need for surgery
- Detect pelvic inflammatory disease or abscess
- Detect uterine fibroids, ovarian cysts, and uterine malformations (ovarian cysts may be aspirated during the procedure)
- Evaluate amenorrhea and infertility
- Evaluate fallopian tubes and anatomic defects to determine the cause of infertility
- Evaluate known or suspected endometriosis, salpingitis, and hydrosalpinx
- Evaluate pelvic pain or masses of unknown cause
- Evaluate reproductive organs after therapy for infertility
- Obtain biopsy specimens to confirm suspected pelvic malignancies or metastasis
- Perform tubal sterilization and ovarian biopsy
- Perform vaginal hysterectomy
- Remove adhesions or foreign bodies such as intrauterine devices (IUDs)
- Treat endometriosis through electrocautery or laser vaporization

RESULT

Normal Findings:

- Normal appearance of uterus, ovaries, fallopian tubes, and other pelvic contents

Abnormal Findings:

- Ectopic pregnancy
- Endometriosis
- Ovarian cyst
- Ovarian tumor
- Pelvic adhesions
- Pelvic inflammatory disease
- Pelvic tumor
- Salpingitis
- Uterine fibroids

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
- Patients with bleeding disorders, especially those associated with uremia and cytotoxic chemotherapy
- Patients with cardiac conditions or dysrhythmias
- Patients with advanced respiratory or cardiovascular disease
- Patients with intestinal obstruction, abdominal mass, abdominal hernia, or suspected intra-abdominal hemorrhage

Factors that may impair clear visualization:

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Patients who are in a hypoxemic or hypercapnic state will require continuous oxygen administration.
- Patients with acute infection or advanced malignancy involving the abdominal wall are at increased risk because organisms may be introduced into the normally sterile peritoneal cavity

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the abdominal and pelvic organs.
- Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, and dyes. Assess if the patient has an allergy to local anesthetics, and inform the health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal, genitourinary, and reproductive systems, as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the

Gastrointestinal, Genitourinary, and Reproductive System tables.

- Ensure that this procedure is performed before an upper gastrointestinal study or barium swallow.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Explain the purpose of the test and how the procedure is performed. Inform the patient that the procedure is performed in a surgery department, usually by a health care practitioner and support staff and takes approximately 30 to 60 minutes.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an intravenous (IV) line may be inserted to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.
- Instruct the patient to fast and restrict fluids for 8 hours prior to the procedure.
- Inform the patient that a laxative and cleansing enema may be needed the day before the procedure, with cleansing enemas on the morning of the procedure, depending on the institution's policy.
- Instruct the patient to remove jewelry (including watches), credit cards, and other metallic objects.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that the patient has complied with dietary, and medication restrictions and pretesting preparations for at least 8 hours prior to the procedure. Ensure the patient has removed all external metallic objects prior to the procedure.
- Ensure that nonallergy to anesthesia is confirmed before the procedure is performed under general anesthesia.
- Assess for completion of bowel preparation according to the institution's procedure.
- Have emergency equipment readily available.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Obtain and record baseline vital signs.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer medications, as ordered, to reduce discomfort and to promote relaxation and sedation.
- Insert an IV line or venous access device at a low "keep open" rate.
- Place the patient on the laparoscopy table. If general anesthesia is to be used, it is administered at this time. Then place the patient in a modified lithotomy position with the head tilted downward. Cleanse the abdomen with an antiseptic solution, and drape and catheterize the patient, if ordered.
- The physician identifies the site for the scope insertion, and administers local anesthesia if that is to be used. After deeper layers are anesthetized, a pneumoperitoneum needle is placed between the visceral and parietal peritoneum.
- CO_2 is insufflated through the pneumoperitoneum needle to separate the abdominal wall from the viscera and to aid in visualization of the abdominal structures. The pneu-

moperitoneum needle is removed, and the trocar and laparoscope are inserted through the incision.

- The physician inserts a uterine manipulator through the vagina and cervix and into the uterus so that the uterus, fallopian tubes, and ovaries can be moved to permit better visualization.
- After the examination, collection of tissue samples, and performance of therapeutic procedures (e.g., tubal ligation), the scope is withdrawn. All possible CO_2 is evacuated via the trocar, which is then removed. The skin incision is closed with sutures, clips, or sterile strips, and a small dressing or adhesive strip is applied. After the perineum is cleansed, the uterine manipulator is removed and a sterile pad applied.

Post-test:

- Monitor vital signs and neurologic status every 15 minutes for 1 hour, then every 2 hours for 4 hours, and as ordered. Take temperature every 4 hours for 24 hours. Compare with baseline values. Notify the health care practitioner if temperature is elevated. Protocols may vary from facility to facility.
- Instruct the patient to resume usual diet, fluids, and medication, as directed by the health care practitioner.
- Instruct the patient to restrict activity for 2 to 7 days after the procedure.
- If indicated, inform the patient of a follow-up appointment for the removal of sutures.
- Inform the patient that shoulder discomfort may be experienced for 1 or 2 days after the procedure as a result of abdominal distention caused by insufflation of CO_2 into the abdomen, and that mild analgesics and cold compresses, as ordered, can be used to relieve the discomfort.
- Emphasize that any persistent shoulder pain, abdominal pain, vaginal bleeding, fever, redness, or swelling of the incisional area must be reported to the health care practitioner immediately.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the abdomen; hepatobiliary scan; kidney, ureter, and bladder study; magnetic resonance imaging of the abdomen; and ultrasound of the abdomen.

LATEX ALLERGY

SYNONYM/ACRONYM: N/A.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Immunoassay) Negative.

DESCRIPTION & RATIONALE: Latex is found in numerous medical supplies, such as gloves, catheters, and bandages. Some individuals who are routinely exposed to latex products, particularly as part of their occupation, have become highly allergic to latex. Health care workers are classified as high risk, especially since the 1987 mandate of standard/universal precautions that resulted in increased use of latex gloves. It is estimated that 8% to 17% of health care workers have become allergic to latex. There are two types of allergic reactions. Type IV allergic contact dermatitis is caused by chemicals used in the process of manufacturing latex. It is a delayed reaction occurring within 6 to 48 hours of direct skin or mucous membrane contact with latex products. The type I allergic reaction occurs in response to proteins in the natural latex products by direct skin or mucous membrane contact or by inhaling aerosolized powder from a latex glove. Other high-risk individuals include people with spina bifida, spinal cord injury, myelodysplasia, atopic dermatitis, eczema, history of allergies (personal or family), history of chronic illness, or multiple surgeries. ■

INDICATIONS: Suspected latex allergy

RESULT

Positive findings in: Latex allergy

Negative findings in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to detect latex sensitivity.
- Obtain a history of the patient's complaints, including a list of known allergens, and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune system, a history of latex exposure, and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune System table.

- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Assist the patient, as appropriate, in identifying sources of exposure in order for the patient to eliminate or reduce the opportunity for continued exposure.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include complete blood count, eosinophil count, and immunoglobulin E.

LEAD

SYNONYM/ACRONYM: Pb.

SPECIMEN: Whole blood (1 mL) collected in a special lead-free royal blue– or tan-top tube. Plasma (1 mL) collected in lavender-top (EDTA) tube is also acceptable.

REFERENCE VALUE: (Method: Atomic absorption spectrophotometry)

	Conventional Units	SI Units (Conventional Units × 0.0483)
Children	0–9.9 μg/dL	0–0.48 μmol/L
Adults	0–25.0 μg/dL	0–1.20 μmol/L
OSHA action limit for occupational exposure	Up to 40 μg/dL	Up to 1.93 μmol/L

OSHA = Occupational Safety and Health Administration.

DESCRIPTION & RATIONALE: Lead is a heavy metal and trace element. It is absorbed through the respiratory and gastrointestinal systems. It can also be transported from mother to fetus through the placenta. When there is frequent exposure to lead-containing items (e.g., paint, batteries, gasoline, pottery, bullets, printing materials) or occupations (mining, automobile, printing, and welding industries), many organs of the body are affected. Lead poisoning can cause severe behavioral and neurologic effects. The blood test is considered the best indicator of lead poisoning, and confirmation is made by the lead mobilization test performed on a 24-hour urine specimen. ■

INDICATIONS: Assist in the diagnosis and treatment of lead poisoning

RESULT

Increased in:

- Anemia of lead intoxication
- Lead encephalopathy
- Metal poisoning

Decreased in: N/A

CRITICAL VALUES:

Levels greater than 30 μg/dL indicate significant exposure.

Levels greater than 60 μg/dL require chelation therapy.

Note and immediately report to the health care practitioner any critically increased values and related symptoms.

INTERFERING FACTORS: Contamination of the collection site and/or specimen with lead in dust can be avoided by taking special care to have the surfaces surrounding the collection location cleaned. Extra care should also be used to avoid contamination during the actual venipuncture.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to detect lead toxicity and monitor exposure to lead.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic System and Therapeutic/Toxicology tables.
- Obtain a history of the patient's exposure to lead.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL royal blue– or tan-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care practitioner regarding further testing, treatment, or referral to another health care practitioner. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be

performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include δ-aminolevulinic acid, complete blood count, erythrocyte protoporphyrin, and urine porphyrins.

LECITHIN/SPHINGOMYELIN RATIO

SYNONYM/ACRONYM: L/S ratio.

SPECIMEN: Amniotic fluid (10 mL) collected in a sterile, brown glass or plastic tube or bottle protected from light.

REFERENCE VALUE: (Method: Thin-layer chromatography)

Mature (nondiabetic): Greater than 2:1 in the presence of phosphatidyl glycerol

Borderline: 1.5 to 1.9:1

Immature: Less than 1.5:1

DESCRIPTION & RATIONALE: Respiratory distress syndrome (RDS) is the most common problem encountered in the care of premature infants. RDS, also called hyaline membrane disease, results from a deficiency of phospholipid lung surfactants. The phospholipids in surfactant are produced by specialized alveolar cells and stored in granular lamellar bodies in the lung. In normally developed lungs, surfactant coats the surface of the alveoli. Surfactant reduces the surface tension of the alveolar wall during breathing. When there is an insufficient quantity of surfactant, the alveoli are unable to expand normally and gas exchange is inhibited. Amniocentesis, a procedure by which fluid is removed from the amniotic sac, is used to assess fetal lung maturity.

Lecithin is the primary surfactant phospholipid, and it is a stabilizing factor for the alveoli. It is produced at a low but constant rate until the 35th week of gestation, after which its production sharply increases. Sphingomyelin, another phospholipid component of surfactant, is also produced at a constant rate after the 26th week of gestation. Before the 35th week, the lecithin/sphingomyelin (L/S) ratio is usually less than 1.6:1. The ratio increases to 2.0 or greater when the rate of lecithin production increases after the 35th week of gestation. Other

phospholipids, such as phosphatidyl glycerol (PG) and phosphatidyl inositol (PI), increase over time in amniotic fluid as well. The presence of PG indicates that the fetus is within 2 to 6 weeks of lung maturity (i.e., at full term). Simultaneous measurement of PG with the L/S ratio improves diagnostic accuracy. Production of phospholipid surfactant is delayed in diabetic mothers. Therefore, caution must be used when interpreting the results obtained from a diabetic patient, and a higher ratio is expected to predict maturity. ■

INDICATIONS:

- Assist in the evaluation of fetal lung maturity
- Determine the optimal time for obstetric intervention in cases of threatened fetal survival caused by stresses related to maternal diabetes, toxemia, hemolytic diseases of the newborn, or postmaturity
- Identify fetuses at risk of developing RDS

RESULT

Increased in:

- Hypertension
- Intrauterine growth retardation
- Malnutrition
- Maternal diabetes
- Placenta previa
- Placental infarction
- Premature rupture of the membranes

Decreased in:

- Advanced maternal age
- Immature fetal lungs
- Multiple gestation
- Polyhydramnios

CRITICAL VALUES:

An L/S ratio less than 1.5:1 is predictive of RDS at the time of delivery.

Note and immediately report to the health care practitioner any critically increased or decreased values and related symptoms. Infants known to be at risk for RDS can be treated with surfactant by intratracheal administration at birth.

INTERFERING FACTORS:

- Fetal blood falsely elevates the L/S ratio.
- Exposing the specimen to light may cause falsely decreased values.
- There is some risk to having an amniocentesis performed, and this should be weighed against the need to obtain the desired diagnostic information. A small percentage (0.5%) of patients have experienced complications including premature rupture of the membranes, premature labor, spontaneous abortion, and stillbirth.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to obtain an estimate of fetal age.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's reproductive and respiratory systems and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. Include any family history of genetic disorders such as cystic fibrosis, Duchenne's muscular dystrophy, hemophilia, sickle cell disease, Tay-Sachs disease, thalassemia, and trisomy 21. Obtain maternal Rh type.

If Rh-negative, check for prior sensitization. A standard RhoGAM dose is indicated after amniocentesis; repeat doses should be considered if repeated amniocentesis is performed. For related laboratory tests, refer to the Reproductive and Respiratory System tables.

- Record the date of the last menstrual period, and determine that the pregnancy is in the third trimester between the 28th and 40th weeks.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Warn the patient that normal results do not guarantee a normal fetus. Assure the patient that precautions to avoid injury to the fetus will be taken by localizing the fetus with ultrasound. Address concerns about pain related to the procedure. Explain that during the transabdominal procedure, any discomfort with a needle biopsy will be minimized with local anesthetics. Patients who are at 20 weeks' gestation or beyond should void before the test, because an empty bladder is less likely to be accidentally punctured during specimen collection. Encourage relaxation and controlled breathing during the procedure to aid in reducing any mild discomfort. Inform the patient that specimen collection is performed by health care practitioner specializing in this procedure and usually takes approximately 20 to 30 minutes to complete.
- *Sensitivity to social and cultural issues*, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that the patient has voided before the procedure if gestation is 21 weeks or more.
- Have emergency equipment readily available.
- Have patient remove clothes below the waist. Assist the patient to a supine position on the exam table with abdomen exposed. Drape the patient's legs, leaving the abdomen exposed. Raise her head or legs slightly to promote comfort and to relax abdominal muscles. If the uterus is large, place a pillow or rolled blanket under the patient's right side to prevent hypertension caused by great-vessel compression.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- Record maternal and fetal baseline vital signs and continue to monitor throughout the procedure. Monitor for uterine contractions. Monitor fetal vital signs using ultrasound. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
- Assess the position of the amniotic fluid, fetus, and placenta using ultrasound.
- Assemble the necessary equipment, including an amniocentesis tray with solution for skin preparation, local anesthetic, 10- or 20-mL syringe, needles of various sizes (including a 22-gauge, 5-inch spinal needle),

sterile drapes, sterile gloves, and foil-covered or amber specimen collection containers.

- Cleanse suprapubic area with an antiseptic solution and protect with sterile drapes. A local anesthetic is injected. Explain that this may cause a stinging sensation.
- A 22-gauge, 5-inch spinal needle is inserted through the abdominal and uterine walls. Explain that a sensation of pressure may be experienced when the needle is inserted. Explain to the patient how to use focusing and controlled breathing for relaxation during the procedure.
- After the fluid is collected and the needle withdrawn, apply slight pressure to the site. Apply a sterile adhesive bandage to the site.
- Monitor the patient for complications related to the procedure (e.g., premature labor, allergic reaction, anaphylaxis).
- Place samples in properly labeled specimen container and promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- ⚠ Fetal heart rate and maternal vital signs (i.e., heart rate, blood pressure, pulse, and respiration) must be compared to baseline values and closely monitored every 15 minutes for 30 to 60 minutes after the amniocentesis procedure. Protocols may vary from facility to facility
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Observe the amniocentesis site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the amniocentesis site. Instruct the patient to report any redness, edema, bleeding, or pain at the site. Instruct the patient to keep the site clean and change the dressing as needed.
- Instruct the patient to expect mild cramping, leakage of small amount of amniotic fluic, and vaginal spotting for up to 2 days following the procedure. Instruct the patient to immediately report moderate to severe abdominal pain or cramps, change in fetal activity, increased or prolonged leaking of amniotic fluid from abdominal needle site, vaginal bleeding that is heavier than spotting, and either chills or fever to the health care practitioner.
- Instruct the patient to rest until all symptoms have disappeared before resuming normal levels of activity.
- Administer standard RhoGAM dose to maternal Rh-negative patients to prevent maternal Rh sensitization should the fetus be Rh-positive.
- Administer mild analgesic and antibiotic therapy as ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and offer support. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Encourage the family to seek counseling if concerned with pregnancy termination or to seek genetic counseling if a chromosomal abnormality is determined. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Decisions regarding elective abortion should take place in the presence of both parents. Pro-

vide a nonjudgmental, nonthreatening atmosphere for discussing the risks and difficulties of delivering and raising a developmentally challenged infant, as well as exploring other options (termination of pregnancy or adoption). It is also important to discuss feelings the mother and father may experience (e.g., guilt, depression, anger) if fetal abnormalities are detected.

- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include amniotic fluid analysis, blood groups and antibodies, chromosome analysis, α-fetoprotein, and Kleihauer-Betke test.

LEUKOCYTE ALKALINE PHOSPHATASE

SYNONYMS/ACRONYM: LAP, LAP score, LAP smear.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

REFERENCE VALUE: (Method: Microscopic evaluation of specially stained blood smears) 32 to 182 (score based on 0 to 4+ rating of 100 neutrophils).

DESCRIPTION & RATIONALE: Alkaline phosphatase is an enzyme important for intracellular metabolic processes. It is present in the cytoplasm of neutrophilic granulocytes from the metamyelocyte to the segmented stage. Leukocyte alkaline phosphatase (LAP) concentrations may be altered by the presence of infection, stress, chronic inflammatory diseases, Hodgkin's disease, and hematologic disorders. Levels are low in leukemic leukocytes and high in normal white blood cells (WBCs), making this test useful as a supportive test in the differential diagnosis of leukemia. It should be noted

that test results must be correlated with the patient's condition because LAP levels increase toward normal in response to therapy. ■

INDICATIONS:

- Differentiate chronic myelocytic leukemia from other disorders that increase the WBC count
- Monitor response of Hodgkin's disease to therapy

RESULT

Increased in:

- Aplastic leukemia
- Chronic inflammation
- Down syndrome
- Hairy cell leukemia
- Hodgkin's disease
- Leukemia (acute and chronic lymphoblastic)
- Myelofibrosis with myeloid metaplasia
- Multiple myeloma
- Polycythemia vera
- Pregnancy
- Stress
- Thrombocytopenia

Decreased in:

- Chronic myelogenous leukemia
- Hereditary hypophosphatemia
- Idiopathic thrombocytopenia purpura
- Nephrotic syndrome
- Paroxysmal nocturnal hemoglobinuria
- Sickle cell anemia
- Sideroblastic anemia

CRITICAL VALUES: N/A

INTERFERING FACTORS: Drugs that may increase the LAP score include steroids.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate disorders of the hematologic system.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic and immune systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic and Immune System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL lavender-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient to avoid exposure to infection if WBC count is decreased.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include bone marrow biopsy and WBC count.

LIPASE

SYNONYM/ACRONYM: Triacylglycerol acylhydrolase.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Spectrophotometry) Plasma values may be 15% lower than serum values.

Conventional & SI Units

40–375 U/L

DESCRIPTION & RATIONALE: Lipases are digestive enzymes secreted by the pancreas into the duodenum. Different lipolytic enzymes have specific substrates, but overall activity is collectively described as lipase. Lipase participates in fat digestion by breaking down triglycerides into fatty acids and glycerol. Lipase is released into the bloodstream when damage occurs to the pancreatic acinar cells. Its presence in the blood indicates pancreatic disease because the pancreas is the only organ that secretes this enzyme. ■

INDICATIONS:

- Assist in the diagnosis of acute and chronic pancreatitis
- Assist in the diagnosis of pancreatic carcinoma

RESULT

Increased in:

- Acute cholecystitis
- Obstruction of the pancreatic duct
- Pancreatic carcinoma (early)
- Pancreatic cyst or pseudocyst
- Pancreatic inflammation
- Pancreatitis (acute and chronic)
- Renal failure (early)

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase lipase levels include asparaginase, azathioprine, cholinergics, codeine, deoxycholate, didanosine, glycocholate, indomethacin, methacholine, methylprednisolone, morphine, narcotics, pancreozymin, pentazocine, and taurocholate.
- Drugs that may decrease lipase levels include protamine and saline (intravenous infusions).
- Endoscopic retrograde cholangiopancreatography may increase lipase levels.
- Serum lipase levels increase with hemodialysis. Therefore, predialysis specimens should be collected for lipase analysis.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to diagnose pancreatitis.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal and hepatobiliary systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Gastrointestinal and Hepatobiliary System tables.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately

5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.

- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Instruct the patient to ingest small, frequent meals if he or she has a gastrointestinal disorder; advise the patient to consider other dietary alterations as well. After acute symptoms subside and bowel sounds return, patients are usually prescribed a clear liquid diet, progressing to a low-fat, high-carbohydrate diet.
- Administer vitamin B_{12}, as ordered, to the patient with decreased lipase levels, especially if his or her disease prevents adequate absorption of the vitamin.
- Encourage the alcoholic patient to avoid alcohol and to seek appropriate counseling for substance abuse.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include alanine aminotransferase, alkaline phosphatase, amylase, aspartate aminotransferase, bilirubin, CA 19-9, calcium, fecal fat, γ-glutamyltranspeptidase, magnesium, mumps serology, pleural fluid amylase, triglycerides, and white blood cell count.

LIPOPROTEIN ELECTROPHORESIS

SYNONYMS/ACRONYMS: Lipid fractionation; lipoprotein phenotyping; $3ga_1$-lipoprotein cholesterol, high-density lipoprotein (HDL); β-lipoprotein cholesterol, low-density lipoprotein (LDL); pre-β-lipoprotein cholesterol, very-low-density lipoprotein (VLDL).

SPECIMEN: Serum (3 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Electrophoresis and 4°C test for specimen appearance) There is no quantitative interpretation of this test. The specimen appearance and electrophoretic pattern is visually interpreted.

Hyperlipoproteinemia: Fredrickson Type	Specimen Appearance	Electrophoretic Pattern
Type I	Clear with creamy top layer	Heavy chylomicron band
Type IIa	Clear	Heavy β band
Type IIb	Clear or faintly turbid	Heavy β and pre-β band
Type III	Slightly to moderately turbid	Heavy β band
Type IV	Slightly to moderately turbid	Heavy pre-β band
Type V	Slightly to moderately turbid with creamy top layer	Intense chylomicron band and heavy pre-β band

DESCRIPTION & RATIONALE: Lipoprotein electrophoresis measures lipoprotein fractions to determine abnormal distribution and concentration of lipoproteins in the serum, an important risk factor in the development of coronary artery disease (CAD). The lipoprotein fractions, in order of increasing density, are (1) chylomicrons, (2) very-low-density lipoprotein (VLDL), (3) low-density lipoprotein (LDL), and (4) high-density lipoprotein (HDL). Chylomicrons and VLDL contain the highest levels of triglycerides and lower amounts of cholesterol and protein. LDL and HDL contain the lowest amounts of triglycerides and relatively higher amounts of cholesterol and protein. ■

INDICATIONS:

- Evaluate known or suspected disorders associated with altered lipoprotein levels
- Evaluate patients with serum choles-

terol levels greater than 250 mg/dL, which indicate a high risk for CAD

- Evaluate the response to treatment for high cholesterol, and determine the need for drug therapy

RESULT:

Type I: Hyperlipoproteinemia or increased chylomicrons can be primary, resulting from an inherited deficiency of lipoprotein lipase; or secondary, caused by uncontrolled diabetes, systemic lupus erythematosus, and dysgammaglobulinemia. Total cholesterol is normal to moderately elevated and triglycerides (mostly exogenous chylomicrons) are grossly elevated. If the condition is inherited, symptoms will appear in childhood.

Type IIa: Hyperlipoproteinemia can be primary, resulting from inherited characteristics, or secondary, caused by hypothyroidism, nephrotic syndrome, and dysgammaglobulinemia. Total cholesterol is elevated, triglycerides are normal, and LDL cholesterol (LDLC) is elevated. If the condition is inherited, symptoms will appear in childhood.

Type IIb: Hyperlipoproteinemia can occur for the same reasons as in type IIa. Total cholesterol, triglycerides, and LDLC are all elevated.

Type III: Hyperlipoproteinemia can be primary, resulting from inherited characteristics; or secondary, caused by hypothyroidism, uncontrolled diabetes, alcoholism, and dysgammaglobulinemia. Total cholesterol and triglycerides are elevated, whereas LDLC is normal.

Type IV: Hyperlipoproteinemia can be primary, resulting from inherited characteristics; or secondary, caused by poorly controlled diabetes, alcoholism, nephrotic syndrome, chronic renal failure, and dysgammaglobulinemia. Total cholesterol is normal to moderately elevated, triglycerides are moderately to grossly elevated, and LDLC is normal.

Type V: Hyperlipoproteinemia can be primary, resulting from inherited characteristics; or secondary, caused by uncontrolled diabetes, alcoholism, nephrotic syndrome, and dysgammaglobulinemia. Total cholesterol is normal to moderately elevated, triglycerides are grossly elevated, and LDLC is normal.

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Failure to follow usual diet for 2 weeks before the test can yield results that do not accurately reflect the patient's cholesterol values.
- Ingestion of alcohol 24 hours before the test, ingestion of food 12 hours before the test, and excessive exercise 12 hours before the test can alter results.
- Numerous drugs can alter results (see monographs titled "Cholesterol, Total" and "Triglycerides").
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

➤ Inform the patient that the test is used to assist in evaluating risk for cardiovascular disease.

- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular system and risk for heart disease, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Cardiovascular System table.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- Instruct the patient to follow his or her usual diet for 2 weeks before testing.
- Instruct the patient to fast and to avoid excessive exercise for at least 12 hours before testing, and to refrain from alcohol consumption for 24 hours before testing.
- There are no medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with dietary and activity restrictions as well as other pretesting preparations; assure that food, fluids, and activity have been restricted for at least 12 hours prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient to resume usual diet, fluids, and activity, as directed by the health care practitioner.
- *Nutritional considerations:* Abnormal lipoprotein electrophoresis patterns may be associated with cardiovascular disease. Nutritional therapy is recommended for the patient identified to be at high risk for developing CAD. If overweight, the patient should be encouraged to achieve a normal weight. The American Heart Association Step 1 and Step 2 diets may be helpful in achieving a goal of lowering total cholesterol and triglyceride levels. The Step 1 diet emphasizes a reduction in foods high in saturated fats and cholesterol. Red meats, eggs, and dairy products are the major sources of saturated fats and cholesterol. If triglycerides also are elevated, the patient should be

advised to eliminate or reduce alcohol and simple carbohydrates from the diet. The Step 2 diet recommends stricter reductions.

- *Social and cultural considerations:* Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 years. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight control education.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association *(http://www.americanheart.org)*.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include antiarrhythmic drugs, apolipoprotein A, apolipoprotein B, aspartate aminotransferase, atrial natriuretic peptide, blood gases, B-type natriuretic peptide, calcium (blood and ionized), cholesterol (total, HDL, and LDL), C-reactive protein, creatine kinase and isoenzymes, glucose, glycated hemoglobin, homocysteine, ketones, lactate dehydrogenase and isoenzymes, magnesium, myoglobin, potassium, triglycerides, and troponin.

LIVER AND SPLEEN SCAN

SYNONYMS/ACRONYM: Liver and spleen scintigraphy, liver-spleen scan, radionuclide liver scan, spleen scan.

AREA OF APPLICATION: Abdomen.

CONTRAST: Intravenous radioactive technetium-99m sulfur colloid.

DESCRIPTION & RATIONALE: The liver and spleen scan is performed to help diagnose abnormalities in the function and structure of the liver and spleen. It is often performed in combination with lung scanning to help diagnose masses or inflammation in the diaphragmatic area. This procedure is useful for evaluating right-upper-quadrant pain, metastatic disease, jaundice, cirrhosis, ascites, traumatic infarction, and radiation-induced organ cellular necrosis. Technetium-99m (Tc-99m) sulfur colloid is injected intravenously and rapidly taken up through phagocytosis by the reticuloendothelial cells, which normally function to remove particulate matter, including radioactive colloids in the liver and spleen. False-negative results may occur in patients with space-occupying lesions (e.g., tumors, cysts, abscesses) smaller than 2 cm. This scan can detect portal hypertension, demonstrated by a greater uptake of the radionuclide in the spleen than in the liver. Single-photon emission computed tomography (SPECT) has significantly improved the resolution and accuracy of liver scanning. SPECT enables images to be recorded from multiple angles around the body and reconstructed by a computer to produce images or "slices" representing the organ at different levels. For evaluation of a suspected hemangioma, the patient's red blood cells are combined with Tc-99m and images are recorded over the liver. To confirm the diagnosis, liver and spleen scans are done in conjunction with computed tomography (CT), magnetic resonance imaging (MRI), ultrasonography, and SPECT scans and interpreted in light of the results of liver function tests. ■

INDICATIONS:

- Assess the condition of the liver and spleen after abdominal trauma
- Detect a bacterial or amebic abscess
- Detect and differentiate between primary and metastatic tumor focal disease
- Detect benign tumors, such as adenoma and cavernous hemangioma
- Detect cystic focal disease
- Detect diffuse hepatocellular disease, such as hepatitis and cirrhosis
- Detect infiltrative processes that affect the liver, such as sarcoidosis and amyloidosis
- Determine superior vena cava obstruction or Budd-Chiari syndrome
- Differentiate between splenomegaly and hepatomegaly
- Evaluate the effects of lower abdominal trauma, such as internal hemorrhage
- Evaluate jaundice
- Evaluate liver and spleen damage caused by radiation therapy or toxic drug therapy
- Evaluate palpable abdominal masses

RESULT

Normal Findings:

- Normal size, contour, position, and function of the liver and spleen

Abnormal Findings:

- Abscesses
- Cirrhosis
- Cysts
- Hemangiomas
- Hematoma
- Hepatitis
- Hodgkin's disease
- Infarction

- Infection
- Infiltrative process (amyloidosis and sarcoidosis)
- Inflammation of the diaphragmatic area
- Metastatic tumors
- Nodular hyperplasia
- Portal hypertension
- Primary benign or malignant tumors
- Traumatic lesions

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined, especially for oblique and decubitus views
- Other nuclear scans done within the preceding 24 to 48 hours

Other considerations:

- The scan may fail to detect focal lesions smaller than 2 cm in diameter.
- Improper injection of the radionuclide may allow the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiologic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses liver and spleen function.
- Obtain a history of the patient's complaints and symptoms, including a list of known allergens.
- Obtain a history of the patient's gastrointestinal and hepatobiliary systems, signs and symptoms of liver and spleen dysfunction, and results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Gastrointestinal and Hepatobiliary System tables.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anti-

coagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.

- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a special department, usually in a radiology department, by a health care practitioner and support staff and takes approximately 30 to 60 minutes.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- The patient should fast and restrict fluids for 8 hours prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.

Intratest:

- Ensure that the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations; assure that food, fluids, and medications have been restricted for at least 8 hours prior to the procedure. Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Record baseline vital signs and assess neurologic status. Protocols may vary from facility to facility.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in a supine position on a flat table with foam wedges, which help maintain position and immobilization. The radionuclide is administered intravenously and the abdomen is scanned immediately for 1 minute to screen for vascular lesions. Then images are taken in the anterior, oblique, lateral, and posterior oblique positions.
- Wear gloves during the radionuclide injection and while handling the patient's urine.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed,

and a pressure dressing is applied over the puncture site.

- The results are recorded on x-ray film or electronically, in a computerized system, for recall and postprocedure interpretation by the appropriate health care practitioner.
- The patient may be imaged by SPECT techniques to further clarify areas of suspicious radionuclide localization.

Post-test:

- Instruct the patient to resume usual diet, fluids, medication, or activity, as directed by the health care practitioner.
- Monitor vital signs and neurologic status every 15 minutes for 1 hour, then every 2 hours for 4 hours, and then as ordered by the health care practitioner. Compare with baseline values. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- Instruct patient to drink increased amounts of fluids for 24 to 48 hours to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hours.
- Instruct the patient to flush the toilet immediately after each voiding following the procedure, and to wash hands meticulously with soap and water after each voiding for 24 hours after the procedure.
- Instruct all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- If a woman who is breast-feeding must have a nuclear scan, she should not breast-feed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- *Nutritional considerations:* A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes. High fat consumption increases the amount of bile acids in the colon and should be avoided.
- No other radionuclide tests should be scheduled for 24 to 48 hours after this procedure.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication.

- Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the abdomen, hepatobiliary scan, liver ultrasound, and magnetic resonance imaging of the abdomen.

LUNG PERFUSION SCAN

SYNONYMS/ACRONYM: Radioactive perfusion scan, lung scintiscan, lung perfusion scintigraphy, ventilation-perfusion scan, pulmonary scan, radionuclide perfusion lung scan, V/Q scan.

AREA OF APPLICATION: Chest/thorax.

CONTRAST: Intravenous radioactive material, usually macroaggregated albumin (MAA).

DESCRIPTION & RATIONALE: The lung perfusion scan is a nuclear medicine study performed to evaluate a patient for pulmonary embolus (PE) or other pulmonary disorders. Technetium (Tc-99m) is injected intravenously and distributed throughout the pulmonary vasculature because of the gravitational effect on perfusion. The scan, which produces a visual image of pulmonary blood flow, is useful in diagnosing or confirming pulmonary vascular obstruction. The diameter of the intravenously injected macroaggregated albumin (MAA) is larger than that of the pulmonary capillaries; therefore, the MAA temporarily becomes lodged in the pulmonary vasculature. A gamma camera detects the radiation emitted from the injected radioactive material, and a representative image of the lung is obtained. This procedure is often done in conjunction with the lung ventilation scan to obtain clinical information that assists in differentiating among the many possible pathologic conditions revealed by the procedure. The results are correlated with other diagnostic studies, such as pulmonary function, chest x-ray, pulmonary angiography, and arterial blood gases. A recent chest x-ray is essential for accurate interpretation of

the lung perfusion scan. An area of nonperfusion seen in the same area as a pulmonary parenchymal abnormality on the chest x-ray indicates that a PE is not present; the defect may represent some other pathologic condition, such as pneumonia. ■

INDICATIONS:

- Aid in the diagnosis of PE in a patient with a normal chest x-ray
- Detect malignant tumor
- Differentiate between PE and other pulmonary diseases, such as pneumonia, pulmonary effusion, atelectasis, asthma, bronchitis, emphysema, and tumors
- Evaluate perfusion changes associated with congestive heart failure and pulmonary hypertension
- Evaluate pulmonary function preoperatively in a patient with pulmonary disease

RESULT

Normal Findings:

- Diffuse and homogeneous uptake of the radioactive material by the lungs

Abnormal Findings:

- Asthma
- Atelectasis
- Bronchitis
- Chronic obstructive pulmonary disease
- Emphysema
- Left atrial or pulmonary hypertension
- Lung displacement by fluid or chest masses
- Pneumonia
- Pneumonitis
- Pulmonary embolism
- Tuberculosis

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
- Patients with atrial and ventricular septal defects, because the MAA particles will not reach the lungs
- Patients with pulmonary hypertension

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined, especially for oblique and decubitus views and for films done by portable equipment
- Other nuclear scans done on the same day

Other considerations:

- Improper injection of the radionuclide may allow the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

- Risks associated with radiologic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses blood flow to the lungs.
- Obtain a history of the patient's complaints and symptoms, including a list of known allergens.
- Obtain a history of the patient's respiratory system, as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Respiratory System table.
- Obtain a history of signs and symptoms of pulmonary embolism, such as sudden sharp chest pain, shortness of breath, chest pain that worsens with deep breathing/coughing, coughing up blood, rapid heart rate, sweating, and/or anxiety.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a special department, usually in a radiology department, by a health care practitioner and support staff and takes approximately 60 minutes.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.

Intratest:

- Ensure that the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations; assure that food, fluids, and medications have been restricted for at least 8 hours prior to the procedure. Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.

- Record baseline vital signs and assess neurologic status. Protocols may vary from facility to facility.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in a supine position on a flat table with foam wedges, which help maintain position and immobilization. The radionuclide is administered intravenously after the syringe is shaken to resuspend the particles. Images of the lungs are obtained in the anterior, posterior, both lateral, and both oblique views.
- Wear gloves during the radionuclide administration and while handling the patient's urine.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- The results are recorded on x-ray film or electronically, in a computerized system, for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, fluids, medication, or activity, as directed by the health care practitioner.
- Monitor vital signs and neurologic status every 15 minutes for 1 hour, then every 2 hours for 4 hours, and then as ordered health care practitioner. Compare with baseline values. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- Instruct patient to drink increased amounts of fluids for 24 to 48 hours to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 24 to 48 hours.
- Instruct the patient to flush the toilet immediately after each voiding following the procedure, and to wash hands meticulously with soap and water after each voiding for 24 hours after the procedure.
- Instruct all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- If a woman who is breast-feeding must have a nuclear scan, she should not breast-feed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- *Nutritional considerations:* A low-fat, low-cholesterol, and low-sodium diet

should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.

- No other radionuclide tests should be scheduled for 24 to 48 hours after this procedure.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include chest x-ray, computed tomography of the thorax and magnetic resonance imaging of the chest.

LUNG VENTILATION SCAN

SYNONYMS/ACRONYM: Radioactive ventilation scan, VQ lung scan, aerosol lung scan, ventilation scan, xenon lung scan.

AREA OF APPLICATION: Chest/thorax.

CONTRAST: Done with inhaled radioactive material (xenon gas or technetium-DTPA).

DESCRIPTION & RATIONALE: The lung ventilation scan is a nuclear medicine study performed to evaluate a patient for pulmonary embolus (PE) or other pulmonary disorders. It can evaluate respiratory function (i.e., demonstrating areas of the lung that are patent and capable of ventilation) and dysfunction (e.g., parenchymal abnormalities affecting ventilation, such as pneumonia). The procedure is performed after the patient inhales air mixed with a radioactive gas through a face mask and mouthpiece. The radioactive gas delineates areas of the lung during ventilation. The distribution of the gas throughout the lung is measured in three phases:

Wash-in phase: Phase during buildup of the radioactive gas

Equilibrium phase: Phase after the patient rebreathes from a closed delivery system

Wash-out phase: Phase after the radioactive gas has been removed

This procedure is usually performed along with a lung perfusion scan. When PE is present, ventilation scans display a normal wash-in and wash-out of radioactivity from the lung areas. Parenchymal disease responsible for perfusion abnormalities will produce abnormal wash-in and wash-out phases. This test can be used to quantify regional ventilation in patients with pulmonary disease. ■

INDICATIONS:

- Aid in the diagnosis of PE
- Differentiate between PE and other pulmonary diseases, such as pneumonia, pulmonary effusion, atelectasis, asthma, bronchitis, emphysema, and tumors
- Evaluate regional respiratory function
- Identify areas of the lung that are capable of ventilation
- Locate hypoventilation (regional), which can result from chronic obstructive pulmonary disease (COPD) or excessive smoking

RESULT

Normal Findings:

- Equal distribution of radioactive gas throughout both lungs and a normal wash-out phase

Abnormal Findings:

- Atelectasis
- Bronchitis
- Bronchogenic carcinoma
- COPD
- Emphysema
- PE
- Pneumonia
- Regional hypoventilation
- Sarcoidosis
- Tuberculosis
- Tumor

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined, especially for oblique and decubitus views and for films done by portable equipment
- Other nuclear scans done within the preceding 24 to 48 hours

Other considerations:

- The presence of conditions that affect perfusion or ventilation (e.g., tumors that obstruct the pulmonary artery, vasculitis, pulmonary edema, sickle cell disease, parasitic disease, emphysema, effusion, infection) can simulate a perfusion defect similar to PE.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses airflow to the lungs.
- Obtain a history of the patient's complaints and symptoms, including a list of known allergens.
- Obtain a history of the patient's respiratory system, as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Respiratory System table.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient's current medications.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Explain the purpose of the test and how the procedure is performed. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department, usually by a technologist and support staff, and takes approximately 30 to 60 minutes.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.

Intratest:

- Make sure jewelry, chains, and any other metallic objects have been removed from the chest area.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Obtain and record baseline vital signs.

- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in a supine position on a flat table with foam wedges, which help maintain position and immobilization. The radionuclide is administered through a mask, which is placed over the patient's nose and mouth. The patient is asked to hold his or her breath for a short period of time while the scan is taken. The distribution of the radioactive gas is monitored and measured on a nuclear scanner. The patient's chest is imaged while the gas is in the lungs. Images of the lungs are obtained in the posterior and, when possible, both oblique views.
- Wear gloves during the radionuclide administration and while handling the patient's urine.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The results are recorded on film or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Evaluate the patient's vital signs. Monitor vital signs every 15 to 30 minutes and compare with baseline readings until the patient is stable.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Advise patient to drink increased amounts of fluids for 24 to 48 hours to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hours.
- Instruct the patient to flush the toilet immediately after each voiding following the procedure, and to wash hands meticulously with soap and water after each voiding for 24 hours after the procedure.
- Tell all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- If a woman who is breast-feeding must have a nuclear scan, she should not breast-feed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or ad-

dress any concerns voiced by the patient or family.

➤ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

➤ Related diagnostic tests include chest x-ray, computed tomography of the thorax, and magnetic resonance imaging of the chest.

LUPUS ANTICOAGULANT ANTIBODIES

SYNONYMS/ACRONYM: Lupus inhibitor phospholipid type, lupus antiphospholipid antibodies.

SPECIMEN: Plasma (1 mL) collected in blue-top (sodium citrate) tube.

REFERENCE VALUE: (Method: Dilute Russell venom viper test time)
Negative.

DESCRIPTION & RATIONALE: Lupus anticoagulant antibodies are immunoglobulins, usually of the immunoglobulin G class. They are also referred to as lupus antiphospholipid antibodies because they interfere with phospholipid-dependent coagulation tests such as activated partial thromboplastin time by reacting with the phospholipids in the test system. They are not associated with a bleeding disorder unless thrombocytopenia or antiprothrombin antibodies are already present. They are associated with an increased risk of thrombosis. ■

INDICATIONS:

- Evaluate prolonged activated partial thromboplastin times
- Investigate reasons for fetal death

RESULT

Positive in:

- Fetal loss
- Raynaud's disease
- Rheumatoid arthritis
- Systemic lupus erythematosus
- Thromboembolism

Negative in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may cause a positive lupus anticoagulant test result include chlorpromazine and heparin.
- Placement of a tourniquet for longer than 1 minute can result in venous stasis and changes in the concentration

of plasma proteins to be measured. Platelet activation may also occur under these conditions, causing erroneous results.

- Vascular injury during phlebotomy can activate platelets and coagulation factors, causing erroneous results.
- Hemolyzed specimens must be rejected because hemolysis is an indication of platelet and coagulation factor activation.
- Incompletely filled tubes contaminated with heparin or clotted specimens must be rejected.
- Icteric or lipemic specimens interfere with optical testing methods, producing erroneous results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate coagulation disorders.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic, immune, musculoskeletal, and reproductive systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic, Immune, Musculoskeletal, and Reproductive System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- Heparin therapy should be discontinued 2 days before specimen collection, with medical direction. Coumarin therapy should be discontinued 2 weeks before specimen collection, with medical direction.
- There are no food or fluid restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with pretesting preparations; assure that anticoagulent therapy has been restricted as required prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL blue-top tube. *Important note:* Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It

is important to inquire from the laboratory which concentration it recommends, because each concentration will have its own specific reference range.

- When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and red-top tubes. When coagulation testing is the only test to be done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with tissue thromboplastin, which can falsely decrease values.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed samples stored in unopened tubes is that testing should be completed within 1 to 4 hours of collection.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient to resume usual medications, as directed by the health care practitioner.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include anticardiolipin antibody, antinuclear antibody, activated partial thromboplastin time, protein S, and rheumatoid factor.

LUTEINIZING HORMONE

SYNONYMS/ACRONYMS: LH, luteotropin, interstitial cell–stimulating hormone (ICSH).

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Immunoassay)

Concentration by Sex and by Phase (in Women)	Conventional Units	SI Units (Conversion Factor ×1)
	Male	
Less than 2 y	0.5–1.9 mIU/mL	0.5–1.9 IU/L
2–10 y	Less than 0.5 mIU/mL	Less than 0.5 IU/L
11–20 y	0.5–5.3 mIU/mL	0.5–5.3 IU/L
Adult	1.2–7.8 mIU/mL	1.2–7.8 IU/L
	Female	
Less than 2–10 y	Less than 0.5 mIU/mL	Less than 0.5 IU/L
11–20 y	0.5–9.0 mIU/mL	0.5–9.0 IU/L
	Phase in Women	
Follicular	1.7–15.0 mIU/mL	1.7–15.0 IU/L
Ovulatory	21.9–56.6 mIU/mL	21.9–56.6 IU/L
Luteal	0.6–16.3 mIU/mL	0.6–16.3 IU/L
Postmenopausal	14.2–52.3 mIU/mL	14.2–52.3 IU/L

DESCRIPTION & RATIONALE:

Luteinizing hormone (LH) is secreted by the anterior pituitary gland in response to stimulation by gonadotropin-releasing hormone, the same hypothalamic releasing factor that stimulates follicle-stimulating hormone release. LH affects gonadal function in both men and women. In women, a surge of LH normally occurs at the midpoint of the menstrual cycle (ovulatory phase); this surge is believed to be induced by high estrogen levels. LH causes the ovum to be expelled from the ovary and stimulates development of the corpus luteum and progesterone production. As progesterone levels rise, LH production decreases. In males, LH stimulates the interstitial cells of Leydig, located in the testes, to produce testosterone. For this reason, in reference to males, LH is sometimes called interstitial cell–stimulating hormone. Secretion of LH is pulsatile and follows a circadian rhythm in response to the normal intermittent secretion of gonadotropin-releasing hormone. ■

INDICATIONS:

- Distinguish between primary and secondary causes of gonadal failure
- Evaluate children with precocious puberty
- Evaluate male and female infertility, as indicated by decreased LH levels
- Evaluate response to therapy to induce ovulation
- Support diagnosis of infertility caused by anovulation, as evidenced by lack of LH surge at the midpoint of the menstrual cycle

RESULT

Increased in:

- Anorchia
- Gonadal failure
- Menopause
- Primary gonadal dysfunction

Decreased in:

- Anorexia nervosa
- Kallmann's syndrome
- Malnutrition
- Pituitary or hypothalamic dysfunction
- Severe stress

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs and hormones that may increase LH levels include clomiphene, gonadotropin-releasing hormone, goserelin, ketoconazole, mestranol, nafarelin, naloxone, nilutamide, spironolactone, and tamoxifen.
- Drugs and hormones that may decrease LH levels include anabolic steroids, anticonvulsants, conjugated estrogens, danazol, digoxin, D-Trp-6-LHRH, estrogen/progestin therapy, goserelin, megestrol, norethindrone, octreotide, oral contraceptives, phenothiazine, pimozide, pravastatin, progesterone, stanozolol, and tamoxifen.
- In menstruating women, values vary in relation to the phase of the menstrual cycle.
- LH secretion follows a circadian rhythm, with higher levels occurring during sleep.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate disorders of the hypothalmic-pituitary-gonadal axis.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine and reproductive systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine and Reproductive System tables.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. If the test is being performed to detect ovulation, inform the patient that it may be necessary to obtain a series of samples over a period of several days to detect peak LH levels. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of col-

lection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.

- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include adrenocorticotropic hormone, antisperm antibody, estradiol, follicle-stimulating hormone, progesterone, prolactin, and testosterone.

LYME ANTIBODY

SYNONYM/ACRONYM: N/A.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Indirect immunofluorescence) Negative.

DESCRIPTION & RATIONALE: *Borrelia burgdorferi,* a deer tick–borne spirochete, is the organism that causes Lyme disease. Lyme disease affects multiple systems and is characterized by fever, arthralgia, and arthritis. The circular, red rash characterizing erythema migrans can appear 3 to 30 days after the tick bite. About one-half of patients in the early stage of Lyme disease (stage 1) and generally all of those in the advanced stage (stage 2)—with cardiac, neurologic, and rheumatoid manifestations—will

have a positive test result. Patients in remission will also have a positive test response. The presence of immunoglobulin M (IgM) antibodies indicates acute infection. The presence of IgG antibodies indicates current or past infection. ■

INDICATIONS: Assist in establishing a diagnosis of Lyme disease

RESULT

Positive findings in: Lyme disease

Negative findings in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- High rheumatoid-factor titers as well as cross-reactivity with Epstein-Barr virus and other spirochetes (e.g., *Rickettsia, Treponema*) may cause false-positive results.
- Positive test results should be confirmed by the Western blot method.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to detect antibodies to *Borrrelia burgdorferi.*
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune and musculoskeletal systems and a history of exposure, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Musculoskeletal System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm diagnosis. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Advise the patient to wear light-colored clothing that covers extremities when in areas infested by deer ticks, and to check body for ticks after returning from infested area.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to perceived loss of independence and fear of shortened life expectancy. Lyme disease can be debilitating and can result in significant changes in lifestyle. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Warn the patient that false-positive test results can occur and that false-negative test results frequently occur. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- A related test is synovial fluid analysis.

LYMPHANGIOGRAPHY

SYNONYM/ACRONYM: Lymphangiogram.

AREA OF APPLICATION: Lymphatic system.

CONTRAST: Intravenous iodine based.

DESCRIPTION: Lymphangiography involves visualization of the lymphatic system after the injection of an iodinated oil–based contrast medium into a lymphatic vessel in the hand or foot. The lymphatic system consists of lymph vessels and nodes. Assessment of this system is important because cancer (lymphomas and Hodgkin's disease) often spreads via the lymphatic system. When the lymphatic system becomes obstructed, painful

edema of the extremities usually results. The procedure is usually performed for cancer staging in patients with an established diagnosis of lymphoma or metastatic tumor. Injection into the hand allows visualization of the axillary and supraclavicular nodes. Injection into the foot allows visualization of the lymphatics of the leg, inguinal and iliac regions, and retroperitoneum up to the thoracic duct. Less commonly, injection into the foot can be used to visualize the cervical region (retroauricular area). This procedure can assess progression of the disease, assist in planning surgery, and monitor the effectiveness of chemotherapy or radiation treatment. ■

INDICATIONS:

- Determine the extent of adenopathy
- Determine lymphatic cancer staging
- Distinguish primary from secondary lymphedema
- Evaluate edema of an extremity without known cause
- Evaluate effects of chemotherapy or radiation therapy
- Plan surgical treatment or evaluate effectiveness of chemotherapy or radiation therapy in controlling malignant tumors

RESULT

Normal Findings:

- Normal lymphatic vessels and nodes that fill completely with contrast medium on the initial films. On the 24-hour films, the lymph nodes are fully opacified and well circumscribed. The lymphatic channels are emptied a few hours after injection of the contrast medium.

Abnormal Findings:

- Abnormal lymphatic vessels
- Hodgkin's disease
- Metastatic tumor involving the lymph glands
- Nodal lymphoma
- Retroperitoneal lymphomas associated with Hodgkin's disease

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with pulmonary insufficiencies, cardiac diseases, or severe renal or hepatic disease.
- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.
- Young patients (17 years old and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Inability to cannulate the lymphatic vessels

Other considerations:

- Be aware of risks associated with the contrast medium. The oil-based contrast medium may embolize into the lungs and will temporarily diminish pulmonary function. This can produce lipid pneumonia, which is a life-threatening complication.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the lymphatic system.
- Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to iodine, seafood, or other contrast mediums.
- Obtain a history of the patient's lymphatic system and previously performed diagnostic procedures, surgical procedures, and laboratory tests. Include specific tests as they apply (e.g., blood urea nitrogen [BUN], creatinine, coagulation tests, platelets, bleeding time). Ensure that the results of blood tests are obtained and recorded before the procedure, especially BUN and creatinine, if contrast medium is to be used. For related diagnostic tests, refer to the Endocrine and Immunologic System tables.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, acetylsalicylic acid, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Inform

the patient that he or she may feel some discomfort when the contrast medium and anesthesia are injected. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed by a health care practitioner and takes 1 to 2 hours. Inform the patient that he or she may have to return the next day, but that this set of images will take only 30 minutes.

- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.
- There are no food or fluid restrictions, unless by medical direction.
- Instruct patient to withhold anticoagulant medication or to reduce dosage before the procedure, as ordered by the health care practitioner.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that the patient has complied with medication restrictions and pretesting preparations. Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily accessible.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Obtain and record baseline vital signs, and assess neurologic status.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer a mild sedative, as ordered.
- Place the patient in a supine position on an x-ray table. Cleanse the selected vein and cover with a sterile drape.
- A local anesthetic is injected at the site, and a small incision is made or a needle inserted. The contrast medium is injected intradermally into the area between the toes or fingers. The lymphatic vessels are identified as the contrast medium moves. A local anesthetic is then injected into the dorsum of each foot or hand, and a small incision is made and cannulated for injection of the contrast medium.
- The contrast medium is then injected, and the flow of the contrast medium is followed by fluoroscopy. When the contrast medium reaches the upper lumbar level, the infusion of contrast medium is discontinued. X-ray images are taken of the chest, abdomen, and pelvis to determine the extent of filling of the lymphatic vessels. Twenty-four–hour delayed images may be taken to examine the lymphatic system after a period of time has elapsed and to monitor the progress of delayed flow.
- Ask the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- Monitor the patient for complications related to the contrast medium (e.g., allergic reaction, anaphylaxis, bronchospasm).
- When the procedure is complete, the cannula is removed and the incision sutured.
- The results are recorded on film or by automated equipment in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Monitor vital signs and neurologic status every 15 minutes for 30 minutes. Compare with baseline values. Protocols may vary from facility to facility.
- Observe for a delayed allergic reaction to contrast medium or pulmonary embolus, which may include shortness of breath, increased heart rate, pleuritic pain, hypotension, low-grade fever, and cyanosis.
- Instruct the patient to resume usual medications, as directed by the health care practitioner.
- Instruct the patient to maintain bed rest up to 24 hours to reduce extremity swelling after the procedure, or as ordered.
- Advise the patient to drink increased amounts of fluids for 24 to 48 hours to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hours.
- Advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, nausea, vomiting, or decreased urinary output.
- Observe the cannula insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the cannulated site, as needed, to reduce discomfort or edema.
- Monitor for signs of infection, such as pain, fever, increased pulse rate, and muscle aches.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the abdomen and pelvis.

MAGNESIUM, BLOOD

SYNONYM/ACRONYM: Mg^{2+}.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Spectrophotometry)

Age	Conventional Units	Alternative Units (Conventional Units × 0.8229)	SI Units (Conventional Units × 0.4114)
Newborn	1.5–2.2 mg/dL	1.23–1.81 mEq/L	0.62–0.91 mmol/L
Child	1.7–2.1 mg/dL	1.40–1.73 mEq/L	0.70–0.86 mmol/L
Adult	1.6–2.6 mg/dL	1.32–2.14 mEq/L	0.66–1.07 mmol/L

DESCRIPTION & RATIONALE: Magnesium is required as a cofactor in numerous crucial enzymatic processes, such as protein synthesis, nucleic acid synthesis, and muscle contraction. Magnesium is also required for the use of adenosine diphosphate as a source of energy. It is the fourth most abundant cation and the second most abundant intracellular ion. Magnesium is needed for the transmission of nerve impulses and muscle relaxation. It controls absorption of sodium, potassium, calcium, and phosphorus; utilization of carbohydrate, lipid, and protein; and activation of enzyme systems that enable the B vitamins to function. Magnesium is also essential for oxidative phosphorylation, nucleic acid synthesis, and blood clotting. Urine magnesium levels reflect magnesium deficiency before serum levels. Magnesium deficiency severe enough to cause hypocalcemia and cardiac arrhythmias can exist despite normal serum magnesium levels. ■

INDICATIONS:

- Determine electrolyte balance in renal failure and chronic alcoholism
- Evaluate cardiac arrhythmias (decreased magnesium levels can lead to excessive ventricular irritability)
- Evaluate known or suspected disorders associated with altered magnesium levels
- Monitor the effects of various drugs on magnesium levels

RESULT

Increased in:

- Addison's disease
- Adrenocortical insufficiency
- Dehydration
- Diabetic acidosis (severe)
- Hypothyroidism
- Multiple myeloma
- Overuse of antacids
- Renal insufficiency
- Systemic lupus erythematosus
- Tissue trauma

Decreased in:

- Alcoholism
- Diabetic acidosis
- Glomerulonephritis (chronic)
- Hemodialysis
- Hyperaldosteronism
- Hypercalcemia
- Hypoparathyroidism
- Inadequate intake
- Inappropriate secretion of antidiuretic hormone
- Long-term hyperalimentation
- Malabsorption
- Pancreatitis
- Pregnancy
- Severe loss of body fluids (diarrhea, lactation, sweating, laxative abuse)

CRITICAL VALUES:

Less than 1.2 mg/dL

Greater than 4.9 mg/dL

Note and immediately report to the health care practitioner any critically increased or decreased values and related symptoms.

Symptoms such as tetany, weakness, dizziness, tremors, hyperactivity, nausea, vomiting, and convulsions occur at decreased (less than 1.2 mg/dL) concentrations. Electrocardiographic (ECG) changes (prolonged P-R and Q-T intervals, broad flat T waves, and ventricular tachycardia) may also occur. Treatment may include administration of magnesium salts, monitoring for respiratory depression and areflexia (intravenous [IV] administration of magnesium salts), and monitoring for diarrhea and metabolic alkalosis (oral administration to replace magnesium).

Respiratory paralysis, decreased reflexes, and cardiac arrest occur at grossly elevated (greater than 15 mg/dL) levels. ECG changes, such as prolonged P-R and Q-T intervals, and bradycardia may be seen. Toxic levels of magnesium may be reversed with the administration of calcium, dialysis treatments, and removal of the source of excessive intake.

INTERFERING FACTORS:

- Drugs that may increase magnesium levels include acetylsalicylic acid and progesterone.
- Drugs that may decrease magnesium levels include albuterol, aminoglycosides, amphotericin B, bendroflumethiazide, chlorthalidone, cisplatin, citrates, cyclosporines, digoxin, gentamicin, glucagon, and oral contraceptives.
- Hemolysis results in a false elevation in values; such specimens should be rejected for analysis.
- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is present in the IV solution, falsely increasing the result.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the evaluation of electrolyte balance.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular, endocrine, gastrointestinal, genitourinary, and reproductive systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Cardiovascular, Endocrine, Gastrointestinal, Genitourinary, and Reproductive System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Educate the magnesium-deficient patient regarding good dietary sources of magnesium, such as green vegetables, seeds, legumes, shrimp, and some bran cereals. Advise the patient that high intake of substances such as phosphorus, calcium, fat, and protein interferes with the absorption of magnesium.
- Instruct the patient to report any signs or symptoms of electrolyte imbalance, such as dehydration, diarrhea, vomiting, or prolonged anorexia.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include antiarrhythmic drugs, aspartate aminotransferase, calcium, C-reactive protein, creatine kinase and isoenzymes, homocysteine, kidney stone analysis, lactate dehydrogenase and isoenzymes, urine magnesium, myoglobin, potassium, troponin, and vitamin D.

MAGNESIUM, URINE

SYNONYMS/ACRONYM: Urine Mg^{2+}.

SPECIMEN: Urine (5 mL) from a random or timed specimen collected in a clean plastic collection container with 6N hydrochloride as a preservative.

REFERENCE VALUE: (Method: Spectrophotometry)

Conventional Units	Alternative Units (Conventional Units × 0.8229)	SI Units (Conventional Units × 0.4114)
7.3–12.2 mg/24 h	6.0–10.0 mEq/24 h	3.0–5.0 mmol/24 h

DESCRIPTION & RATIONALE: Magnesium is required as a cofactor in numerous crucial enzymatic processes, such as protein synthesis, nucleic acid synthesis, and muscle contraction. Magnesium is also required for the use of adenosine diphosphate as a source of energy. It is the fourth most abundant cation and the second most abundant intracellular ion. Magnesium is needed for the transmission of nerve impulses and muscle relaxation. It controls absorption of sodium, potassium, calcium, and phosphorus; utilization of carbohydrate, lipid, and protein; and activation of enzyme systems that enable the B vitamins to function. Magnesium is also essential for oxidative phosphorylation, nucleic acid synthesis, and blood clotting. Urine magnesium levels reflect magnesium deficiency before serum levels. Magnesium deficiency severe enough to cause hypocalcemia and cardiac arrhythmias can exist despite normal serum magnesium levels.

Regulating electrolyte balance is one of the major functions of the kidneys. In normally functioning kidneys, urine levels increase when serum levels are high and decrease when serum levels are low to maintain homeostasis. Analyzing these urinary levels can provide important clues as to the functioning of the kidneys and other major organs. Tests for electrolytes, such as magnesium, in urine usually involve timed urine collections over a 12- or 24-hour period. Measurement of random specimens may also be requested. ■

INDICATIONS:

- Determine the potential cause of renal calculi
- Evaluate known or suspected endocrine disorder

- Evaluate known or suspected renal disease
- Evaluate magnesium imbalance
- Evaluate a malabsorption problem

Result

Increased in:

- Alcoholism
- Bartter's syndrome
- Transplant recipients on cyclosporine and prednisone
- Use of corticosteroids
- Use of diuretics

Decreased in:

- Abnormal renal function
- Crohn's disease
- Inappropriate secretion of antidiuretic hormone
- Salt-losing conditions

Critical Values: N/A

Interfering Factors:

- Drugs that may increase urine magnesium levels include cisplatin, cyclosporine, ethacrynic acid, furosemide, mercaptomerin, mercurial diuretics, and thiazides.
- Drugs that may decrease urine magnesium levels include amiloride, angiotensin, oral contraceptives, parathyroid extract, and phosphates.
- Magnesium levels follow a circadian rhythm, and for this reason 24-hour collections are recommended.
- All urine voided for the timed collection period must be included in the collection, or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate magnesium balance.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine, gastrointestinal, and genitourinary systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine, Gastrointestinal, and Genitourinary System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
- Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to

pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to avoid excessive exercise and stress during the 24-hour collection of urine.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with activity restrictions during the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection.

Random specimen (collect in early morning):

Clean-catch specimen:

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling catheter:

- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 minutes before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Timed specimen:

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container's label the amount of urine, test start

and stop times, and ingestion of any foods or medications that can affect test results.

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- *Nutritional considerations:* Educate the magnesium-deficient patient regarding good dietary sources of magnesium, such as green vegetables, seeds, legumes, shrimp, and some bran cereals. Advise the patient that high intake of substances such as phosphorus, calcium, fat, and protein interferes with the absorption of magnesium.
- Instruct the patient to report any signs or symptoms of electrolyte imbalance, such as dehydration, diarrhea, vomiting, or prolonged anorexia.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include calcium, kidney stone analysis, magnesium, phosphorus, potassium, and vitamin D.

MAGNETIC RESONANCE ANGIOGRAPHY

SYNONYM/ACRONYM: MRA.

AREA OF APPLICATION: Vascular.

CONTRAST: Can be done with or without intravenous (IV) contrast (gadolinium).

DESCRIPTION & RATIONALE: Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position, this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of the vessels in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography. MRA is particularly useful for visualizing vascular abnormalities, dissections, and other pathology. Special imaging sequences allow the visualization of moving blood within the vascular system. Two common techniques to obtain images of flowing blood are time-of-flight and phase-contrast MRA. In time-of-flight imaging, incoming blood makes the vessels appear bright and surrounding tissue is suppressed. Phase-contrast images are produced by subtracting the stationary tissue surrounding the vessels where the blood is moving through vessels during the imaging, producing high-contrast images. MRA is the most accurate technique for imaging blood flowing in veins and small arteries (*laminar flow*), but it does not accurately depict blood flow in tortuous sections of vessels and distal to bifurcations and stenosis. Swirling blood may cause a signal loss and result in inadequate images, and the degree of vessel stenosis may be overestimated. Images can be obtained in two-dimensional (series of slices) or three-dimensional sequences. ■

INDICATIONS:

- Detect pericardial abnormalities
- Detect peripheral vascular disease
- Detect thoracic and abdominal vascular diseases
- Determine renal artery stenosis
- Differentiate aortic aneurysms from tumors near the aorta
- Evaluate cardiac chambers and pulmonary vessels
- Evaluate postoperative angioplasty sites and bypass grafts
- Identify congenital vascular diseases
- Monitor and evaluate the effectiveness of medical or surgical treatment

RESULT

Normal Findings:

- Normal blood flow in the area being examined, including blood flow rate

Abnormal Findings:

- Coarctations
- Dissections
- Thrombosis within a vessel
- Tumor invasion of a vessel
- Vascular abnormalities
- Vessel occlusion
- Vessel stenosis

CRITICAL VALUES: N/A

INTERFERING FACTORS

This procedure is contraindicated for:

- Patients with certain ferrous metal prosthetics, valves, aneurysm clips, inner ear prostheses, or other metallic objects
- Patients with metal in their body, such as shrapnel or ferrous metal in the eye
- Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
- Patients who are claustrophobic
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Metallic objects within the examination field (e.g., jewelry, body rings, dental amalgams), which may inhibit organ visualization and can produce unclear images
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients with extreme cases of claustrophobia, unless sedation is given before the study

Other considerations:

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the vascular system.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to contrast medium), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular system, as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Cardiovascular System table.
- Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- Note any recent procedures that can interfere with test results.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Inform the patient that the procedure is performed in an MRI department, usually by a technologist and support staff, and takes approximately 30 to 60 minutes.
- Inform the patient that the technologist will place him or her in a supine

position on a flat table in a large cylindrical scanner.

- Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.

Intratest:

- Ensure that the patient has removed jewelry, dentures, all external metallic objects etc. prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Supply earplugs to the patient to block out the loud, banging sounds that occur during the test.
- If an electrocardiogram or respiratory gating is to be performed in conjunction with the scan, apply MRI-safe electrodes to the appropriate sites.
- The patient can communicate with the technologist during the examination via a microphone within the machine.
- Establish intravenous fluid line for the injection of emergency drugs, and sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in the supine position on an exam table.
- If ordered with contrast, the contrast medium is injected, and a series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to monitor the venous phase of the procedure.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The results are recorded on film or on automated equipment in a computerized system for recall and post-procedure interpretation by the appropriate health care practitioner.

Post-test:

- If contrast is administered, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching or decreased urinary output
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as

needed, to reduce discomfort or edema.

- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Explain the importance of adhering to the therapy regimen. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include angiography of the body area of interest, computed tomography angiography, and ultrasound arterial Doppler carotid and venous Doppler ultrasound.

MAGNETIC RESONANCE IMAGING, ABDOMEN

SYNONYM/ACRONYM: Abdominal MRI.

AREA OF APPLICATION: Liver/abdominal area.

CONTRAST: Can be done with or without intravenous (IV) contrast medium (gadolinium).

DESCRIPTION & RATIONALE: Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radiofrequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position; this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system.

MRI produces cross-sectional images of the abdomen in multiple planes without the use of ionizing radiation or the interference of bone.

Abdominal MRI is performed to assist in diagnosing abnormalities of abdominal and hepatic structures. Contrast-enhanced imaging is effective for distinguishing peritoneal metastases from primary tumors of the gastrointestinal tract. Primary tumors of the stomach, pancreas, colon, and appendix often spread by intraperitoneal tumor shedding and subsequent peritoneal carcinomatosis. MRI uses the noniodinated contrast medium gadopentetate dimeglumine (Magnevist), which is administered intravenously to enhance contrast differences between normal and abnormal tissues.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography (see monograph titled "Magnetic Resonance Angiography"). When the Food and Drug Administration approves gastrointestinal contrast agents, these agents would assist in identifying areas of bowel wall thickening, stricture, and intraluminal abnormalities, such as tumors, sites of perforation, and fistula. ■

INDICATIONS:

- Detect abdominal aortic diseases
- Detect and stage cancer (primary or metastatic tumors of liver, pancreas, prostate, uterus, and bladder)
- Detect chronic pancreatitis
- Detect renal vein thrombosis
- Detect soft tissue abnormalities
- Determine and monitor tissue damage in renal transplant patients
- Determine the presence of blood clots, cysts, fluid or fat accumulation in tissues, hemorrhage, and infarctions
- Determine vascular complications of pancreatitis, venous thrombosis, or pseudoaneurysm
- Differentiate aortic aneurysms from tumors near the aorta
- Differentiate liver tumors from liver abnormalities, such as cysts, cavernous hemangiomas, and hepatic amebic abscesses
- Evaluate postoperative angioplasty sites and bypass grafts
- Monitor and evaluate the effectiveness of medical or surgical interventions and the course of the disease

RESULT

Normal Findings:

- Normal anatomic structures, soft tissue density, and biochemical constituents of body tissues, including blood flow

Abnormal Findings:

- Acute tubular necrosis
- Aneurysm
- Cholangitis
- Glomerulonephritis
- Hydronephrosis
- Internal bleeding
- Masses, lesions, infections, or inflammations
- Renal vein thrombosis
- Vena cava obstruction

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
- Patients with metal in their body, such as shrapnel or ferrous metal in the eye
- Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
- Patients with intrauterine devices
- Patients with iron pigments in tattoos
- Patients who are claustrophobic
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Metallic objects within the examination field (e.g., jewelry, body rings, dental amalgams), which may inhibit organ visualization and can produce unclear images
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized

Other considerations:

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the organs and structures inside the abdomen.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to contrast medium), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal, genitourinary, and hepatobiliary systems, as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. Ensure that the results of blood tests are obtained and recorded before the procedure, especially coagulation tests, blood urea nitrogen, and creatinine, if contrast medium is to be used. For related diagnostic tests, refer to the Gastrointestinal, Genitourinary, and Hepatobiliary System tables.
- Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to

the patient that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that, if contrast is used, the radionuclide poses no radioactive hazard and rarely produces side effescts. Inform the patient that the procedure is performed in an MRI department, usually by a technologist and support staff, and takes approximately 30 to 60 minutes.

- Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Supply earplugs to the patient to block out the loud, banging sounds that occur during the test.
- The patient can communicate with the technologist during the examination via a microphone within the machine.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in the supine position on an exam table.
- If ordered with contrast, the contrast medium is injected, and a series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to monitor the venous phase of the procedure.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed,

and a pressure dressing is applied over the puncture site.

- The results are recorded on film or on automated equipment in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting, if contrast medium was used.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching or decreased urinary output
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- No other radionuclide tests should be scheduled for 24 to 48 hours after this procedure.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Explain the importance of adhering to the therapy regimen. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include angiography of the abdomen; computed tomography of the abdomen; kidney, ureter, and bladder (KUB) study; and ultrasound of the liver and biliary system.

MAGNETIC RESONANCE IMAGING, BRAIN

SYNONYM/ACRONYM: Brain MRI.

AREA OF APPLICATION: Brain area.

CONTRAST: Can be done with or without intravenous (IV) contrast medium (gadolinium).

DESCRIPTION & RATIONALE: Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radiofrequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position, this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of pathologic lesions of the brain in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue.

Brain MRI can distinguish solid, cystic, and hemorrhagic components of lesions. This procedure is done to aid in the diagnosis of intracranial abnormalities, including tumors, ischemia, infection, and multiple sclerosis, and in assessment of brain maturation in pediatric patients. Rapidly flowing blood on spin-echo MRI appears as an absence of signal or a void in the vessel's lumen. Blood flow can be evaluated in the cavernous and carotid arteries. Aneurysms may be diagnosed without traditional iodine-based contrastangiography, and old clotted blood in the walls of the aneurysms appears white. MRI uses the noniodinated contrast medium gadopentetate dimeglumine (Magnevist), which is administered intravenously to enhance contrast differences between normal and abnormal tissues.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography (see monograph titled "Magnetic Resonance Angiography"). ■

INDICATIONS:

- Detect and locate brain tumors
- Detect cause of cerebrovascular accident, cerebral infarct, or hemorrhage
- Detect cranial bone, face, throat, and neck soft tissue lesions
- Evaluate the cause of seizures, such as intracranial infection, edema, or increased intracranial pressure
- Evaluate cerebral changes associated with dementia
- Evaluate demyelinating disorders
- Evaluate intracranial infections
- Evaluate optic and auditory nerves
- Evaluate the potential causes of headache, visual loss, and vomiting
- Evaluate shunt placement and function in patients with hydrocephalus
- Evaluate the solid, cystic, and hemorrhagic components of lesions
- Evaluate vascularity of the brain and vascular integrity
- Monitor and evaluate the effectiveness of medical or surgical interventions, chemotherapy, and radiation therapy and the course of disease

RESULT

Normal Findings:

- Normal anatomic structures, soft tissue density, blood flow rate, face, nasopharynx, neck, tongue, and brain

Abnormal Findings:

- Abscess
- Acoustic neuroma
- Alzheimer's disease
- Aneurysm
- Arteriovenous malformation
- Benign meningioma
- Cerebral aneurysm
- Cerebral infarction
- Craniopharyngioma or meningioma
- Granuloma
- Intraparenchymal hematoma or hemorrhage
- Lipoma
- Metastasis
- Multiple sclerosis
- Optic nerve tumor
- Parkinson's disease
- Pituitary microadenoma
- Subdural empyema
- Ventriculitis

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
- Patients with metal in their body, such as shrapnel or ferrous metal in the eye
- Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
- Patients with intrauterine devices
- Patients with iron pigments in tattoos
- Patients who are claustrophobic
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Metallic objects within the examination field (e.g., jewelry, body rings, dental amalgams), which may inhibit organ visualization and can produce unclear images
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized

Other considerations:

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the brain.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to contrast medium), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular and endocrine systems,

as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Cardiovascular and Endocrine System tables.

- Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Inform the patient that the procedure is performed in an MRI department, usually by a technologist and support staff, and takes approximately 30 to 60 minutes.
- Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Supply earplugs to the patient to block out the loud, banging sounds that occur during the test.
- If an electrocardiogram or respiratory gating is to be performed in conjunction with the scan, apply MRI-safe electrodes to the appropriate sites.
- The patient can communicate with the technologist during the examination via a microphone within the machine.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

- Place the patient in the supine position on an exam table.
- If ordered with contrast, the contrast medium is injected, and a series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to monitor the venous phase of the procedure.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- The results are recorded on film or on automated equipment in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting, if contrast medium was used.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching or decreased urinary output
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Explain the importance of adhering to the therapy regimen. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include angiography of the carotids, computed tomography of the brain, and positron emission tomography scan of the brain.

MAGNETIC RESONANCE IMAGING, BREAST

SYNONYM/ACRONYM: Breast MRI.

AREA OF APPLICATION: Breast area.

CONTRAST: Can be done with or without intravenous (IV) contrast medium (gadolinium).

DESCRIPTION & RATIONALE: Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radiofrequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position, this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of the pathologic lesions in multiple planes without the use of ionizing radiation or the interference of surrounding tissue, breast implants, or surgically implanted clips.

MRI imaging of the breast is not a replacement for traditional mammography, ultrasound, or biopsy. This exam is extremely helpful in evaluating mammogram abnormalities and identifying early breast cancer in women at high risk. High-risk women include those who have had breast cancer, have an abnormal mutated breast cancer gene (*BRCA1* or *BRCA2*), or have a mother or sister who has been diagnosed with breast cancer. Breast MRI is used most commonly in high-risk women when findings of a mammogram or ultrasound are inconclusive because of dense breast tissue or there is a suspected abnormality that requires further evaluation. MRI is also an excellent exam in the augemented breast, including both the breast implant itself and the breast tissue surrounding the implant. This same exam is also useful for staging breast cancer and determining the most appropriate treatment. MRI uses the noniodinated contrast medium gadopentetate dimeglumine (Magnevist), which is administered intravenously to enhance contrast differences between normal and abnormal tissues. ■

INDICATIONS:

- Evaluate breast implants
- Evaluate dense breasts
- Evaluate for residual cancer after lumpectomy

- Evaluate inverted nipples
- Evaluate small abnormalities
- Evaluate tissue after lumpectomy or mastectomy
- Evaluate women at high risk for breast cancer

Result

Normal Findings:

- Normal anatomic structures, soft tissue density, and blood flow rate

Abnormal Findings:

- Breast abscess or cyst
- Breast cancer
- Breast implant rupture
- Hematoma
- Soft tissue masses
- Vascular abnormalities

Critical Values: N/A

Interfering Factors:

This procedure is contraindicated for:

- Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
- Patients with metal in their body, such as shrapnel or ferrous metal in the eye
- Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
- Patients with intrauterine devices
- Patients with iron pigments in tattoos
- Patients who are claustrophobic
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized

Other considerations:

- The procedure may take 30 to 60 minutes to complete, and may require the injection of contrast material.
- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.
- The procedure can be nonspecific; the exam is unable to image calcifications that can indicate breast cancer, and there may be difficulty distinguishing between cancerous and noncancerous tumors.
- The procedure is not widely available, and costs significantly more than a mammogram or ultrasound.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the breast.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or

sensitivities to contrast medium), and inform the appropriate health care practitioner accordingly.

- Obtain a history of the patient's reproductive system, as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Reproductive System table.
- Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Inform the patient that the procedure is performed in an MRI department, usually by a technologist and support staff, and takes approximately 30 to 60 minutes.
- Inform the patient that the technologist will place him or her in a prone position on a special imaging table in a large cylindrical scanner.
- Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Supply earplugs to the patient to block out the loud, banging sounds that occur during the test.
- The patient can communicate with the technologist during the examination via a microphone within the machine.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

- Place the patient in the prone position on a special exam table designed for breast imaging.
- If ordered with contrast, the contrast medium is injected, and a series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to monitor the venous phase of the procedure.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- The results are recorded on film or on automated equipment in a computerized system for recall and post-procedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting, if contrast medium was used.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching or decreased urinary output
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Explain the importance of adhering to the therapy regimen. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include bone scan, computed tomography of the thorax, mammogram, sterotatic biopsy of the breast, and ultrasound of the breast.

MAGNETIC RESONANCE IMAGING, CHEST

SYNONYM/ACRONYM: Chest MRI.

AREA OF APPLICATION: Chest/thorax.

CONTRAST: Can be done with or without intravenous (IV) contrast medium (gadolinium).

DESCRIPTION & RATIONALE: Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radiofrequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position, this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of pathologic lesions in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue.

Chest MRI scanning is performed to assist in diagnosing abnormalities of cardiovascular and pulmonary structures. Two special techniques are available for evaluation of cardiovascular structures. One is the electrocardiograph (ECG)–gated multislice spin-echo sequence, used to diagnose anatomic abnormalities of the heart and aorta, and the other is the ECG-referenced gradient refocused sequence, used to diagnose heart function and analyze blood flow patterns.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography (see monograph titled "Magnetic Resonance Angiography"). ■

INDICATIONS:

- Confirm diagnosis of cardiac and pericardiac masses
- Detect aortic aneurysms
- Detect myocardial infarction and cardiac muscle ischemia
- Detect pericardial abnormalities
- Detect pleural effusion
- Detect thoracic aortic diseases
- Determine blood, fluid, or fat accumu-

lation in tissues, pleuritic space, or vessels
- Determine cardiac ventricular function
- Differentiate aortic aneurysms from tumors near the aorta
- Evaluate cardiac chambers and pulmonary vessels
- Evaluate postoperative angioplasty sites and bypass grafts
- Identify congenital heart diseases
- Monitor and evaluate the effectiveness of medical or surgical therapeutic regimen

Result

Normal Findings:
- Normal heart and lung structures, soft tissue, and function, including blood flow rate

Abnormal Findings:
- Aortic dissection
- Congenital heart diseases, including pulmonary atresia, aortic coarctation, agenesis of the pulmonary artery, and transposition of the great vessels
- Constrictive pericarditis
- Intramural and periaortic hematoma
- Myocardial infarction
- Pericardial hematoma or effusion
- Pleural effusion

Critical Values: N/A

Interfering Factors:

This procedure is contraindicated for:
- Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
- Patients with metal in their body, such as shrapnel or ferrous metal in the eye
- Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
- Patients with intrauterine devices
- Patients with iron pigments in tattoos
- Patients who are claustrophobic
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
- Metallic objects within the examination field (e.g., jewelry, body rings, dental amalgams), which may inhibit organ visualization and can produce unclear images
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized

Other considerations:
- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the organs and structures inside the chest.
- Obtain a history of the patient's com-

plaints, including a list of known allergens (especially allergies or sensitivities to contrast medium), and inform the appropriate health care practitioner accordingly.

- Obtain a history of the patient's cardiovascular and respiratory systems, as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Cardiovascular and Respiratory System tables.
- Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium.
- Record the date of the last menstrual period and the determine possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Inform the patient that the procedure is performed in an MRI department, usually by a technologist and support staff, and takes approximately 30 to 60 minutes.
- Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Supply earplugs to the patient to block out the loud, banging sounds that occur during the test.
- If an electrocardiogram or respiratory gating is to be performed in conjunction with the scan, apply MRI-safe electrodes to the appropriate sites.
- The patient can communicate with the technologist during the examination via a microphone within the machine.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.

- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in the supine position on an exam table.
- If ordered with contrast, the contrast medium is injected, and a series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to monitor the venous phase of the procedure.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- The results are recorded on film or on automated equipment in a computerized system for recall and post-procedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting, if contrast medium was used.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching or decreased urinary output
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Explain the importance of adhering to the therapy regimen. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include chest x-ray, computed tomography of the thorax, echocardiography, myocardial infarct scan, mycardial perfusion heart scan, and positron emission tomography scan of the heart.

MAGNETIC RESONANCE IMAGING, MUSCULOSKELETAL

SYNONYM/ACRONYM: Musculoskeletal (knee, shoulder, hand, wrist, foot, elbow, hip) MRI.

AREA OF APPLICATION: Bones, joints, soft tissues.

CONTRAST: Can be done with or without intravenous (IV) contrast medium (gadolinium).

DESCRIPTION & RATIONALE: Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radiofrequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position, this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of bones and joints in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue.

Musculoskeletal MRI is performed to assist in diagnosing abnormalities of bones and joints and surrounding soft tissue structures, including cartilage, synovium, ligaments, and tendons. MRI eliminates the risks associated with exposure to x-rays and causes no harm to cells. Contrast-enhanced imaging is effective for evaluating scarring from previous surgery, vascular abnormalities, and differentiation of metastases from primary tumors. MRI uses the noniodinated contrast medium gadopentetate dimeglumine (Magnevist), which is administered intravenously to enhance contrast differences between normal and abnormal tissues.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography (see monograph titled "Magnetic Resonance Angiography"). ■

INDICATIONS:

- Confirm diagnosis of osteomyelitis
- Detect avascular necrosis of the femoral head or knee
- Detect benign and cancerous tumors and cysts of the bone or soft tissue

- Detect bone infarcts in the epiphyseal or diaphyseal sites
- Detect changes in bone marrow
- Detect tears or degeneration of ligaments, tendons, and menisci resulting from trauma or pathology
- Determine cause of low back pain, including herniated disk and spinal degenerative disease
- Differentiate between primary and secondary malignant processes of the bone marrow
- Differentiate between a stress fracture and a tumor
- Evaluate meniscal detachment of the temporomandibular joint

Result

Normal Findings:

- Normal bones, joints, and surrounding tissue structures; no articular disease, bone marrow disorders, tumors, infections, or trauma to the bones, joints, or muscles

Abnormal Findings:

- Avascular necrosis of femoral head or knee, as found in Legg-Calvé-Perthes disease
- Bone marrow disease, such as Gaucher's disease, aplastic anemia, sickle cell disease, or polycythemia
- Degenerative spinal disease, such as spondylosis or arthritis
- Fibrosarcoma
- Hemangioma (muscular or osseous)
- Herniated disk
- Infection
- Meniscal tears or degeneration
- Osteochondroma
- Osteogenic sarcoma
- Osteomyelitis
- Rotator cuff tears
- Spinal stenosis
- Stress fracture
- Synovitis
- Tumor

Critical Values: N/A

Interfering Factors:

This procedure is contraindicated for:

- Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
- Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
- Patients with metal in their body, such as shrapnel or ferrous metal in the eye
- Patients with intrauterine devices
- Patients with iron pigments in tattoos
- Patients who are claustrophobic
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Metallic objects within the examination field (e.g., jewelry, body rings, dental amalgams), which may inhibit organ visualization and can produce unclear images
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized

Other considerations:

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses muscles, bones, and joints.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to contrast medium), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular and musculoskeletal systems, as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Cardiovascular and Musculoskeletal System tables.
- Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Inform the patient that the procedure is performed in an MRI department, usually by a technologist and support staff, and takes approximately 30 to 60 minutes.
- Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylac-

tic steroids or antihistamines before the procedure.

- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Supply earplugs to the patient to block out the loud, banging sounds that occur during the test.
- The patient can communicate with the technologist during the examination via a microphone within the machine.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in the supine position on an exam table.
- If ordered with contrast, the contrast medium is injected, and a series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to monitor the venous phase of the procedure.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- The results are recorded on film or on automated equipment in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting, if contrast medium was used.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching or decreased urinary output
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Explain the importance of adhering to the therapy regimen. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include arthroscopy, bone mineral densitometry, bone scan, and radiography of the bone.

MAGNETIC RESONANCE IMAGING, PANCREAS

SYNONYM/ACRONYM: Pancreatic MRI.

AREA OF APPLICATION: Pancreatic/upper abdominal area.

CONTRAST: Can be done with or without intravenous (IV) contrast medium (gadolinium).

DESCRIPTION & RATIONALE: Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radiofrequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position, this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of the abdominal area in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue.

MRI of the pancreas is employed to evaluate small pancreatic adenocarcinomas, islet cell tumors, ductal abnormalities and calculi, or parenchymal abnormalities. A T1-weighted, fat-saturation series of images is probably best for evaluating the pancreatic parenchyma. This sequence is ideal for showing fat planes between the pancreas and peripancreatic structures and for identifying abnormalities, such as fatty infiltration of the pancreas, hemorrhage, adenopathy, and carcinomas. T2-weighted images are most useful for depicting intrapancreatic or peripancreatic fluid collections, pancreatic neoplasms, and calculi. Imaging sequences can be adjusted to display fluid in the biliary tree and pancreatic ducts. MRI uses the noniodinated contrast medium gadopentetate dimeglumine (Magnevist), which is administered intravenously to enhance contrast differences between normal and abnormal tissues.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography (see monograph titled "Magnetic Resonance Angiography"). When the Food and Drug Administration approves gas-

trointestinal contrast agents, they may be useful for delineating the exact relationship among the stomach, duodenum, and proximal jejunum and the pancreas. These agents would assist in identifying areas of bowel wall thickening, stricture, and intraluminal abnormalities, such as tumors, sites of perforation, and fistula. ■

INDICATIONS:

- Detect pancreatic fatty infiltration, hemorrhage, and adenopathy
- Detect a pancreatic mass
- Detect pancreatitis
- Detect primary or metastatic tumors of the pancreas and provide cancer staging
- Detect soft tissue abnormalities
- Determine vascular complications of pancreatitis, venous thrombosis, or pseudoaneurysm
- Differentiate tumors from other abnormalities, such as cysts, cavernous hemangiomas, and pancreatic abscesses
- Monitor and evaluate the effectiveness of medical or surgical interventions and course of disease

RESULT

Normal Findings:

- Normal anatomic structures and soft tissue density and biochemical constituents of the pancreatic parenchyma, including blood flow

Abnormal Findings:

- Islet cell tumor
- Metastasis
- Pancreatic duct obstruction or calculi
- Pancreatic fatty infiltration, hemorrhage, and adenopathy
- Pancreatic mass
- Pancreatitis

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
- Patients with metal in their body, such as shrapnel or ferrous metal in the eye
- Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
- Patients with intrauterine devices
- Patients with iron pigments in tattoos
- Patients who are claustrophobic
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Metallic objects within the examination field (e.g., jewelry, body rings, dental amalgams), which may inhibit organ visualization and can produce unclear images
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized

Other considerations:

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the pancreas and the organs and structures inside the abdomen.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to contrast medium), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hepatobiliary and endocrine systems, as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Hepatobiliary and Endocrine System tables.
- Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Inform the patient that the procedure is performed in an MRI department, usually by a technologist and support staff, and takes approximately 30 to 60 minutes.
- Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.

- Supply earplugs to the patient to block out the loud, banging sounds that occur during the test.
- The patient can communicate with the technologist during the examination via a microphone within the machine.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in the supine position on an exam table.
- If ordered with contrast, the contrast medium is injected, and a series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to monitor the venous phase of the procedure.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- The results are recorded on film or on automated equipment in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting, if contrast medium was used.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching or decreased urinary output
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Explain the importance of adhering to the therapy regimen. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic and laboratory tests include amylase, angiography of the abdomen, computed tomography of the abdomen, hepatobiliary scan; 5-hydroxyindoleacetic acid, lipase, ultrasound of the liver and biliary system, and ultrasound of the pancreas.

MAGNETIC RESONANCE IMAGING, PELVIS

SYNONYM/ACRONYM: Pelvic MRI.

AREA OF APPLICATION: Pelvic area.

CONTRAST: Can be done with or without intravenous (IV) contrast (gadolinium).

DESCRIPTION & RATIONALE: Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radiofrequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position, this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of the pelvic area in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue.

Pelvic MRI is performed to assist in diagnosing abnormalities of the pelvis and associated structures. Contrast-enhanced MRI is effective for evaluating metastases from primary tumors. MRI is highly effective for depicting small-volume peritoneal tumors, carcinomatosis, and peritonitis and for determining the response to surgical and chemical therapies. MRI uses the noniodinated contrast medium gadopentetate dimeglumine (Magnevist), which is administered intravenously to enhance contrast differences between normal and abnormal tissues. Oral and rectal contrast administration may be used to isolate the bowel from adjacent pelvic organs and improve organ visualization.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography (see monograph titled "Magnetic Resonance Angiography"). When the Food and Drug Administration approves gastrointestinal contrast agents, these agents would assist in identifying areas of bowel wall thickening, stricture, and intraluminal abnormalities, such as tumors, sites of perforation, and fistula. ■

INDICATIONS:

- Detect cancer (primary or metastatic tumors of ovary, prostate, uterus, and bladder) and provide cancer staging
- Detect pelvic vascular diseases
- Detect peritonitis
- Detect soft tissue abnormalities
- Determine blood clots, cysts, fluid or fat accumulation in tissues, hemorrhage, and infarctions
- Differentiate tumors from tissue abnormalities, such as cysts, cavernous hemangiomas, and abscesses
- Monitor and evaluate the effectiveness of medical or surgical interventions and course of the disease

RESULT

Normal Findings:

- Normal pelvic structures and soft tissue density and biochemical constituents of pelvic tissues, including blood flow

Abnormal Findings:

- Adenomyosis
- Ascites
- Fibroids
- Masses, lesions, infections, or inflammations
- Peritoneal tumor or carcinomatosis
- Peritonitis
- Pseudomyxoma peritonei

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
- Patients with metal in their body, such as shrapnel or ferrous metal in the eye
- Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
- Patients with intrauterine devices
- Patients with iron pigments in tattoos
- Patients who are claustrophobic
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Metallic objects within the examination field (e.g., jewelry, body rings, dental amalgams), which may inhibit organ visualization and can produce unclear images
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized

Other considerations:

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the organs and structures inside the pelvis and lower abdomen.

- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to contrast medium), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal and genitourinary systems, as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Gastrointestinal and Genitourinary System tables.
- Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Inform the patient that the procedure is performed in an MRI department, usually by a technologist and support staff, and takes approximately 30 to 60 minutes.
- Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Supply earplugs to the patient to block out the loud, banging sounds that occur during the test.
- The patient can communicate with the technologist during the examination via a microphone within the machine.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a

child or to an uncooperative adult, as ordered.

- Place the patient in the supine position on an exam table.
- If ordered with contrast, the contrast medium is injected, and a series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to monitor the venous phase of the procedure.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- The results are recorded on film or on automated equipment in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting, if contrast medium was used.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching or decreased urinary output.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Explain the importance of adhering to the therapy regimen. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the pelvis; kidney, ureter, and bladder (KUB) study; and ultrasound of the pelvis.

MAGNETIC RESONANCE IMAGING, PITUITARY

SYNONYMS/ACRONYM: Pituitary MRI, MRI of the perisellar region.

AREA OF APPLICATION: Brain/pituitary area.

CONTRAST: Can be done with or without intravenous (IV) contrast medium (gadolinium).

DESCRIPTION & RATIONALE: Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radiofrequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position, this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of the pituitary and perisellar region in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue.

Pituitary MRI shows the relationship of pituitary lesions to the optic chiasm and cavernous sinuses. MRI has the capability of distinguishing the solid, cystic, and hemorrhagic components of lesions. Rapidly flowing blood on spin-echo MRI appears as an absence of signal or a void in the vessel's lumen. Blood flow can be evaluated in the cavernous and carotid arteries. Suprasellar aneurysms may be diagnosed without angiography, and old clotted blood in the walls of the aneurysms appears white. MRI uses the noniodinated contrast medium gadopentetate dimeglumine (Magnevist), which is administered intravenously to enhance contrast differences between normal and abnormal tissues.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography (see monograph titled "Magnetic Resonance Angiography"). ■

INDICATIONS:

- Detect microadenoma or macroadenoma of the pituitary
- Detect perisellar abnormalities
- Detect tumors of the pituitary

- Evaluate potential cause of headache, visual loss, and vomiting
- Evaluate the solid, cystic, and hemorrhagic components of lesions
- Evaluate vascularity of the pituitary
- Monitor and evaluate the effectiveness of medical or surgical interventions and course of disease

Result

Normal Findings:

- Normal anatomic structures, density, and biochemical constituents of the pituitary, including blood flow

Abnormal Findings:

- Abscess
- Aneurysm
- Choristoma
- Craniopharyngioma or meningioma
- Empty sella
- Granuloma
- Infarct or hemorrhage
- Macroadenoma or microadenoma
- Metastasis
- Parasitic infection

Critical Values: N/A

Interfering Factors:

This procedure is contraindicated for:

- Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
- Patients with metal in their body, such as shrapnel or ferrous metal in the eye
- Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
- Patients with intrauterine devices
- Patients with iron pigments in tattoos
- Patients who are claustrophobic
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Metallic objects within the examination field (e.g., jewelry, body rings, dental amalgams), which may inhibit organ visualization and can produce unclear images
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized

Other considerations:

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the pituitary and surrounding brain tissue.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to contrast medium), and inform the appropriate health care practitioner accordingly.

- Obtain a history of the patient's cardiovascular and endocrine systems, as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Cardiovascular and Endocrine System tables.
- Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Inform the patient that the procedure is performed in an MRI department, usually by a technologist and support staff, and takes approximately 30 to 60 minutes.
- Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Supply earplugs to the patient to block out the loud, banging sounds that occur during the test.
- The patient can communicate with the technologist during the examination via a microphone within the machine.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in the supine position on an exam table.

- If ordered with contrast, the contrast medium is injected, and a series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to monitor the venous phase of the procedure.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- The results are recorded on film or on automated equipment in a computerized system for recall and post-procedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting, if contrast medium was used.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching or decreased urinary output
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Explain the importance of adhering to the therapy regimen. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the brain, electroencephalography, magnetic resonance imaging of the brain, and positron emission tomography of the brain.

MAMMOGRAPHY

SYNONYMS/ACRONYM: Mammogram, breast x-ray.

AREA OF APPLICATION: Breast.

CONTRAST: None.

DESCRIPTION & RATIONALE: Mammography, an x-ray examination of the breast, is most commonly used to detect breast cancer; however, it can also be used to detect and evaluate symptomatic changes associated with other breast diseases, including mastitis, abscess, cystic changes, cysts, benign tumors, masses, and lymph nodes. Mammography is usually performed with traditional x-ray film, but totally electronic image recording is becoming commonplace. This type of radiologic procedure reduces the amount of radiation exposure to the patient and produces detailed images with excellent contrast. Two views of each breast are usually taken. Benign cysts appear as clearly defined, regular, clear spots that are bilateral; cancer appears as irregular, poorly defined, unilateral opaque areas or clusters of calcifications. Mammography can be used to locate a nonpalpable lesion for biopsy. Mammography cannot detect breast cancer with 100% accuracy: In approximately 15% of breast cancer cases, the cancer is not detected with mammography. To assist in early detection of nonpalpable breast lesions, computer-assisted diagnosis is currently being used. With this technique, a computer performs automated scanning of the mammogram before the physician interprets the findings.

When a mass is detected, additional studies are performed to help differentiate the nature of the mass, as follows:

Magnification views of the area in question

Focal or "spot" views of the area in question, done with a specialized paddle-style compression device

Ultrasound images of the area in question, which help differentiate between a fluid-filled cystic lesion and a solid lesion indicative of cancer

The American Cancer Society recommends that all women follow a personal breast-care plan according to age:

Women ages 20 to 39: Clinical breast examination performed by a health care professional every 3 years and a monthly breast self-examination

Women ages 40 and older: Annual mammogram, clinical breast examination every year by a health care professional (near time of the mammogram), and monthly breast self-examination. ■

INDICATIONS:

- Differentiate between benign and neoplastic breast disease
- Evaluate breast pain, skin retraction, nipple erosion, or nipple discharge
- Evaluate known or suspected breast cancer
- Evaluate nonpalpable breast masses
- Evaluate opposite breast after mastectomy
- Monitor postoperative and post–radiation treatment status of the breast
- Evaluate size, shape, and position of breast masses

RESULT

Normal Findings:

- Normal breast tissue, with no cysts, tumors, or calcifications

Abnormal Findings:

- Breast calcifications
- Breast cysts or abscesses
- Breast tumors
- Hematoma resulting from trauma
- Mastitis
- Soft-tissue masses
- Vascular calcification

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
- Patients younger than age 25, because the density of the breast tissue is such that diagnostic x-rays are of limited value

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Application of substances such as talcum powder or creams to the skin of breasts or underarms, which may alter test results
- Previous breast surgery, breast augmentation, or the presence of breast implants, which may decrease the readability of the examination

Other considerations:

- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding infants of patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses breast status.
- Obtain a history of the patient's symptoms and complaints.
- Obtain a history of known or suspected breast disease, and family history of breast disease, or breast biopsies.
- Obtain a history of results of previously performed diagnostic procedures and surgical procedures. For related diagnostic tests, refer to the Reproductive System table.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Inform the patient there may be discomfort associated with the study, while the breast is being compressed, but that the compression allows for better visualization of the breast tissue. Explain to the patient that the radiation dose will be kept to an absolute minimum. Inform the patient that the procedure is performed in the mammography department by a registered radiologic techologist and takes approximately 15 to 30 minutes to complete.
- Inform the patient that the best time to schedule the examination is 1 week after menses, when breast tenderness is decreased.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- Inform the patient not to apply deodorant, body creams, or powders on the day of the procedure.
- Instruct the patient to remove jewelry and other metallic objects from the field of examination.

Intratest:

- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Make sure jewelry, chains, and any other metallic objects have been removed from the chest area.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions and follow the general guidelines in Appendix A.
- Assist the patient to a standing or sitting position in front of the x-ray machine, which is adjusted to the level of the breasts. Position the patient's arms out of the range of the area to be filmed.
- Place breasts, one at a time, between the compression apparatus. Usually two views or exposures are taken of each breast. Ask the patient to hold her breath during exposures.
- The results are recorded on a sheet of x-ray film or electronically, in a computerized system, for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Determine if patient or family members have any further questions or concerns.
- Educate the patient regarding the techniques for breast self-examination.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will

be sent to the requesting health care practitioner, who will discuss the results with the patient.

- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include breast biopsy, bone scan, computed tomography scan of the thorax, and ultrasound of the breast.

MECKEL'S DIVERTICULUM SCAN

SYNONYMS/ACRONYM: Meckel's scan, Meckel's scintigraphy, ectopic gastric mucosa scan.

AREA OF APPLICATION: Abdomen.

CONTRAST: Intravenous radioactive technetium-99m pertechnetate.

DESCRIPTION & RATIONALE: Meckel's diverticulum scan is a nuclear medicine study performed to assist in diagnosing the cause of abdominal pain or occult gastrointestinal (GI) bleeding, and to assess the presence and size of a congenital anomaly of the GI tract. After intravenous injection of technetium-99m pertechnetate, immediate and delayed imaging is performed, with various views of the abdomen obtained. The radionuclide is taken up and concentrated by parietal cells of the gastric mucosa, whether located in the stomach or in a Meckel's diverticulum. Up to 25% of Meckel's diverticulum is lined internally with ectopic gastric mucosal tissue. This tissue is usually located in the ileum and right lower quadrant of the abdomen; it secretes acid that causes ulceration of intestinal tissue, which results in abdominal pain and occult blood in stools. ■

INDICATIONS:

- Aid in the diagnosis of unexplained abdominal pain and GI bleeding caused by hydrochloric acid and pepsin secreted by ectopic gastric mucosa, which ulcerates nearby mucosa
- Detect sites of ectopic gastric mucosa

RESULT

Normal Findings:

- Normal distribution of radionuclide by gastric mucosa at normal sites

Abnormal Findings:

- Meckel's diverticulum, as evidenced by focally increased radioactive uptake in areas other than normal structures

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Retained barium from a previous radiologic procedure
- Other nuclear scans done within the preceding 24 hours

Other considerations:

- False-positive results may occur from nondiverticular bleeding, intussusception, duplication cysts, inflammatory bowel disease, hemangioma of the bowel, and other organ infections.
- Inadequate amount of gastric mucosa within Meckel's diverticulum can affect the ability to visualize abnormalities.
- Inaccurate timing for imaging after the radionuclide injection can affect the results.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses GI bleeding.
- Obtain a history of the patient's com-

plaints and symptoms, including a list of known allergens.

- Obtain a history of the patient's gastrointestinal and cardiovascular systems, as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Gastrointestinal and Cardiovascular System tables.
- Obtain a history of signs and symptoms of Meckel's diverticulum, such as bleeding, pain, intussusception, volvulus, or diverticulitis.
- Note any recent procedures that can interfere with test results.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a special department, usually in a radiology department, by a health care practitioner and support staff, and takes approximately 60 minutes.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an intravenous (IV) line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- Ensure that a histamine blocker is administered, as ordered, 2 days before the study to block GI secretion, as appropriate.
- Occasionally, gastrin is given to increase the uptake of the radionuclide by the ectopic gastric mucosa.
- The patient should fast and restrict fluids for 8 hours prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.

Intratest:

- Ensure that the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations; assure that food and medications have been restricted for at least 8 hours prior to the procedure. Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Record baseline vital signs and assess neurologic status. Protocols may vary from facility to facility.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in a supine position on a flat table with foam wedges,

which help maintain position and immobilization. The radionuclide is administered intravenously, and the abdomen is scanned immediately for 1 minute to screen for vascular lesions that cause bleeding. Then images are taken every 5 minutes for the next 60 minutes in the anterior, oblique, and lateral views, and then in a single postvoid anterior view.

- Wear gloves during the radionuclide injection and while handling the patient's urine.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- The results are recorded on x-ray film or electronically, in a computerized system, for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, fluids, and medications, as directed by the health care practitioner.
- Monitor vital signs and neurologic status every 15 minutes for 1 hour, then every 2 hours for 4 hours, and then as ordered by the health care practitioner. Compare with baseline values. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- Instruct patient to drink increased amounts of fluids for 24 to 48 hours to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hours.
- Instruct the patient to flush the toilet immediately after each voiding following the procedure, and to wash hands meticulously with soap and water after each voiding for 24 hours after the procedure.
- Instruct all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- If a woman who is breast-feeding must have a nuclear scan, she should not breast-feed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- *Nutritional considerations:* A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes. High fat consumption increases the amount of bile acids in the colon and should be avoided.
- No other radionuclide tests should be scheduled for 24 to 48 hours after this procedure.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information

regarding the clinical implications of the test results, as appropriate.

- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the abdomen or pelvis, and magnetic resonance imaging of the abdomen or pelvis.

MEDIASTINOSCOPY

SYNONYM/ACRONYM: N/A.

AREA OF APPLICATION: Mediastinum.

CONTRAST: None.

DESCRIPTION & RATIONALE: Mediastinoscopy provides direct visualization of the structures that lie beneath the mediastinum, which is the area behind the sternum and between the lungs. The test is performed under general anesthesia by means of a mediastinoscope inserted through a surgical incision at the suprasternal notch. Structures that can be viewed include the trachea, the esophagus, the heart and its major vessels, the thymus gland, and the lymph nodes that receive drainage from the lungs. The procedure is performed primarily to visualize and obtain biopsy specimens of the mediastinal lymph nodes, and to determine the extent of metastasis into the mediastinum for the determination of treatment planning in cancer patients. ■

INDICATIONS:

- Confirm radiologic evidence of a thoracic infectious process of an indeterminate nature, coccidioidomycosis, or histoplasmosis
- Confirm radiologic or cytologic evidence of carcinoma or sarcoidosis
- Detect Hodgkin's disease

- Detect metastasis into the anterior mediastinum or extrapleurally into the chest
- Determine stage of known bronchogenic carcinoma, as indicated by the extent of mediastinal lymph node involvement
- Evaluate a patient with signs and symptoms of obstruction of mediastinal lymph flow and a history of head or neck cancer to determine recurrence or spread

Result

Normal Findings:

- Normal appearance of mediastinal structures
- No abnormal lymph node tissue

Abnormal Findings:

- Bronchogenic carcinoma
- Coccidioidomycosis
- Granulomatous infections
- Histoplasmosis
- Hodgkin's disease
- *Pneumocystis carinii* infection
- Sarcoidosis
- Tuberculosis

Critical Values: N/A

Interfering Factors:

This procedure is contraindicated for:

- Patients who have had a previous mediastinoscopy, because scarring can make insertion of the scope and biopsy of lymph nodes difficult
- Patients who have superior vena cava obstruction, because this condition causes increased venous collateral circulation in the mediastinum
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Other considerations:

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the mediastinum.
- Obtain a history of the patient's complaints or symptoms, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune and respiratory systems, any bleeding disorders, and results of previously performed laboratory tests (especially bleeding time, complete blood count, partial thromboplastin time, platelets, and prothrombin time), surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Respiratory System tables.
- Note any recent procedures that can interfere with test results. Ensure that this procedure is performed before an upper gastrointestinal study or barium swallow.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, acetylsalicylic acid, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation. It is recommended that use be discontinued 14 days before dental or surgical procedures. The requesting health care practitioner and laboratory should be

advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.

- Review the procedure with the patient. Inform the patient that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain related to the procedure. Explain that a general anesthesia will be administered to promote relaxation and reduce discomfort prior to the mediastinoscopy. Explain to the patient that some pain may be experienced after the test. Meperidine (Demerol) or morphine may be given as a sedative. Inform the patient that the procedure is performed in the operating room, under sterile conditions, by a health care practitioner specializing in this procedure. The procedure usually takes about 30 to 60 minutes to complete.
- Explain that an intravenous (IV) line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- The patient should fast and restrict fluids for 8 hours prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- Ensure that the results of blood typing and cross-matching are obtained and recorded before the procedure in the event that an emergency thoracotomy is required.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations; assure that food and fluids have been restricted for at least 8 hours prior to the procedure. Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Ensure that anticoagulant therapy has been withheld for the appropriate amount of days prior to the procedure. Notify the health care practitioner if patient anticoagulant therapy has not been withheld.
- Have emergency equipment readily available. Keep resuscitation equipment on hand in the case of respiratory impairment or laryngospasm after the procedure.
- Avoid using morphine sulfate in patients with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs and assess neurologic status. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Establish IV fluid line for the injection of emergency drugs and of sedatives.
- Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.
- Place the patient in the supine position. General anesthesia is administered via an endotracheal tube.
- An incision is made at the suprasternal notch, and a path for the medi-

astinoscope is made using finger dissection. The lymph nodes can be palpated at this time. The lymph nodes on the right side of the mediastinum are most accessible and safest to biopsy by medastinoscopy; the lymph nodes on the left side are more difficult to explore and biopsy because of their proximity to the aorta. Biopsy specimens of nodes on the left side of the mediastinum may need to be obtained by mediastinotomy, which involves performing a left anterior thoracotomy.

- Place tissue samples in properly labeled specimen containers, and promptly transport the specimen to the laboratory for processing and analysis.
- The scope is removed, and the incision is closed.
- If the patient is stable and if no further surgery is immediately indicated, the patient is extubated.

Post-test:

- The patient should remain in a semi-Fowler's position on either side until vital signs revert to preprocedure levels.
- Monitor vital signs and neurologic status every 15 minutes for 1 hour, then every 2 hours for 4 hours, and then as ordered by the health care practitioner. Take temperature every 4 hours for 24 hours. Compare with baseline values. Notify the health care practitioner if temperature is elevated. Protocols may vary from facility to facility.
- Do not allow the patient to eat or drink for 12 to 24 hours. Instruct the patient to resume normal activity, medication, and diet in 24 hours or as tolerated after the examination, unless otherwise indicated.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Instruct the patient in the care and assessment of the site. Observe the site for bleeding, hematoma formation, and inflammation. Note any pleuritic pain, persistent right shoulder pain, or chest pain.
- *Nutritional considerations:* A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.
- Emphasize that any excessive bleeding, difficulty breathing, excessive coughing after biopsy, or pain must be reported to the health care practitioner immediately.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be

needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

Related diagnostic tests include chest x-ray, computed tomography of the thorax, lung scan, and magnetic resonance imaging of the chest.

METANEPHRINES

SYNONYM/ACRONYM: N/A.

SPECIMEN: Urine (25 mL) from a timed specimen collected in a clean amber plastic collection container with 6N hydrochloride as a preservative.

REFERENCE VALUE: (Method: High-pressure liquid chromatography)

Age	Conventional Units	SI Units
	Normetanephrines	
		(Conventional Units × 5.46)
0–3 mo	47–156 μg/24 h	257–852 nmol/24 h
4–6 mo	31–111 μg/24 h	171–607 nmol/24 h
7–9 mo	42–109 μg/24 h	230–595 nmol/24 h
10–12 mo	23–103 μg/24 h	127–562 nmol/24 h
1–2 y	32–118 μg/24 h	175–647 nmol/24 h

10–16 y	39–243 μg/24 h	200–1231 nmol/24 h
Adult	45–290 μg/24 h	228–1470 nmol/24 h

DESCRIPTION & RATIONALE:

Metanephrines are the inactive metabolites of epinephrine and norepinephrine. Metanephrines are either excreted or further metabolized into vanillylmandelic acid. Release of metanephrines in the urine is indicative of disorders associated with excessive catecholamine production, particularly pheochromocytoma. Vanillylmandelic acid and catecholamines are normally measured with urinary metanephrines. Creatinine is usually measured simultaneously to ensure adequate collection and to calculate an excretion ratio of metabolite to creatinine. ■

INDICATIONS:

- Assist in the diagnosis of suspected pheochromocytoma
- Assist in identifying the cause of hypertension
- Verify suspected tumors associated with excessive catecholamine secretion

RESULT

Increased in:

- Ganglioneuroma
- Neuroblastoma
- Pheochromocytoma
- Severe stress

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase metanephrine levels include labetalol, monoamine oxidase inhibitors, oxprenolol, oxytetracycline, and prochlorperazine.
- Methylglucamine in x-ray contrast medium may cause false-negative results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the diagnosis of pheochromocytoma, neuroblastoma, and ganglioblastoma.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine System table.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
- Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine

into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to avoid excessive exercise and stress during the 24-hour collection of urine.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with activity restrictions during the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

Timed specimen:

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container's label the amount of urine and test start and stop times.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual activity, as directed by the health care practitioner.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the

patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include catecholamines, homovanillic acid, and vanillylmandelic acid.

METHEMOGLOBIN

SYNONYMS/ACRONYM: Hemoglobin, hemoglobin M, MetHb, Hgb M.

SPECIMEN: Whole blood (1 mL) collected in green-top (heparin) tube. Specimen should be transported tightly capped and in an ice slurry.

REFERENCE VALUE: (Method: Spectrophotometry)

Conventional Units	SI Units (Conventional Units × 155)
0.06–0.24 g/dL*	9.3–37.2 μmol/L*

* Percentage of total hemoglobin = 0.41–1.15%.
Note: The conversion factor of ×155 is based on the molecular weight of hemoglobin of 64,500 daltons (d), or 64.5 kd.

DESCRIPTION & RATIONALE: Methemoglobin is a structural hemoglobin variant formed when the heme portion of the deoxygenated hemoglobin is oxidized to a ferric state that renders it incapable of combining with and transporting oxygen to tissues. Visible cyanosis can result as levels approach 10% to 15% of total hemoglobin. ■

INDICATIONS:

- Assist in the detection of acquired methemoglobinemia caused by the toxic effects of chemicals and drugs
- Assist in the detection of congenital methemoglobinemia, indicated by deficiency of red blood cell nicotinamide adenine dinucleotide (NADH)-methemoglobin reductase or presence of methemoglobin.
- Evaluate cyanosis in the presence of normal blood gases

RESULT

Increased in:

- Acquired methemoglobinemia (drugs, tobacco smoking, or ionizing radiation)
- Carbon monoxide poisoning

- Hereditary methemoglobinemia (deficiency of NADH-methemoglobin reductase or hemoglobinopathy)

Decreased in: N/A

CRITICAL VALUES:

Cyanosis can occur at levels greater than 10%.

Dizziness, fatigue, headache, and tachycardia can occur at levels greater than 30%.

Signs of central nervous system depression can occur at levels greater than 45%.

Death may occur at levels greater than 70%.

Note and immediately report to the health care practitioner any critically increased or decreased values and related symptoms. Possible interventions include airway protection, administration of oxygen, monitoring neurologic status every hour, continuous pulse oximetry, hyperbaric oxygen therapy, and exchange transfusion. Administration of activated charcoal or gastric lavage may be effective if performed soon after the toxic agent is ingested. Emesis should never be induced in patients with no gag reflex because of the risk of aspiration. Methylene blue may be used to reverse the process of methemoglobin formation, but it should be used cautiously when methemoglobin levels are greater than 30%. Use of methylene blue is contraindicated in the presence of glucose-6-phosphate dehydrogenase deficiency.

INTERFERING FACTORS:

- Drugs that may increase methemoglobin levels include acetanilid, amyl nitrate, aniline derivatives, benzocaine, chlorates, chloroquine, dapsone, glucosulfone, isoniazid, lidocaine, nitroglycerin, phenacetin, phenytoin, primaquine, resorcinol, sulfonamides, and thiazolsulfone.
- Well water containing nitrate is the most common cause of methemoglobinemia in infants.
- Breast-feeding infants are capable of converting inorganic nitrate from common topical anesthetic applications containing nitrate to the nitrite ion, causing nitrite toxicity and increased methemoglobin.
- Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results. Methemoglobin is unstable and should be transported on ice within a few hours of collection, or else the specimen should be rejected.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to investigate cyanosis associated with polycythemia, hemoglobinopathies, and drug toxicity (inhaled substances).
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic and respiratory systems and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic and Respiratory System tables.
- Note any recent procedures that can interfere with test results.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns

about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.

- There are no food, fluid, or medication restrictions, unless by medical direction.
- Prepare an ice slurry in a cup or plastic bag to have on hand for immediate transport of the specimen to the laboratory.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL green-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis. The specimen should be placed in an ice slurry immediately after collection. Information on the specimen label can be protected from water in the ice slurry if the specimen is first placed in a protective plastic bag.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Teach the patient to avoid carbon monoxide from first- or second-hand smoking, to have home gas furnace checked yearly for leaks, and to utilize gas appliances such as gas grills in a well-ventilated area.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include arterial/alveolar oxygen ratio, blood gases, carboxyhemoglobin, and hemoglobin electrophoresis.

MICROALBUMIN

SYNONYMS/ACRONYM: Albumin, urine.

SPECIMEN: Urine (10 mL) from a random or timed specimen collected in a clean plastic collection container.

REFERENCE VALUE: (Method: Nephelometry immunoassay)

Test	Conventional Units	SI Units (Conventional Units × 0.001)
Random microalbumin	0–30 mg/L	0–0.03 g/L
24-h microalbumin	Greater than 40 μg/24 h	Greater than 0.04 g/24 h

Simultaneous measurement of urine creatinine or creatinine clearance may be requested. Normal ratio of microalbumin to creatinine is less than 15.

DESCRIPTION & RATIONALE: The term *microalbumin* is used to describe concentrations of albumin in urine that are greater than normal but undetectable by dipstick or traditional spectrophotometry methods. Microalbuminuria precedes the nephropathy associated with diabetes and is often elevated years before creatinine clearance shows abnormal values. Studies have shown that the median duration from onset of microalbuminuria to development of nephropathy is 5 to 7 years. ■

INDICATIONS:

- Evaluate renal disease
- Screen diabetic patients for early signs of nephropathy

RESULT

Increased in:

- Cardiomyopathy
- Diabetic nephropathy
- Exercise
- Hypertension (uncontrolled)
- Pre-eclampsia
- Renal disease
- Urinary tract infections

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may decrease microalbumin levels include captopril, dipyridamole, enalapril, furosemide, indapamide, perindopril, quinapril, ramipril, tolrestat, and triflusal.
- All urine voided for the timed collection period must be included in the collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the mangement of early diabetes in order to avoid or delay the onset of renal disease associated with diabetes.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine and genitourinary systems as well as results results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine and Genitourinary System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
- Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to avoid excessive exercise and stress during the 24-hour collection of urine.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with activity restrictions during the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

Random specimen (collect in early morning):

Clean-catch specimen:

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine

stream, void directly into the specimen container.

Indwelling catheter:

- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 minutes before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Timed specimen:

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container's label the amount of urine and test start and stop times.

General:

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual activity, as directed by the health care practitioner.
- Instruct the patient and caregiver to report signs and symptoms of hypoglycemia or hyperglycemia.
- *Nutritional considerations:* Instruct the patient, as appropriate, in nutritional management of diabetes. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. There is no "diabetic diet"; however, there are many meal-planning approaches with nutritional goals endorsed by the American Dietetic Association. The nutritional needs of each diabetic patient need to be determined individually with the appropriate health care professionals, particularly professionals trained in nutrition.
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, if indicated, that good glycemic control delays the onset and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services, as appropriate. Provide contact information, if desired, for the American Diabetes Association *(http://www.diabetes.org)*.

- A written report of the examination will be sent to the requesting health care practitioner who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include cortisol, urine creatinine, creatinine clearance, glucose, glucose tolerance test, glycated hemoglobin, insulin, insulin antibodies, urinalysis, and urine protein and fractions.

β_2-MICROGLOBULIN

SYNONYM/ACRONYM: β_2-M.

SPECIMEN: Serum (1 mL) collected in a red-top tube or 5 mL urine from a timed collection in a clean plastic container with 1N NaOH as a preservative.

REFERENCE VALUE: (Method: Immunoassay for serum sample, radioimmunoassay for urine sample)

Sample	Conventional Units	SI Units (Conventional Units × 10)
Serum		
Newborn	Less than 0.3 mg/dL	Less than 3 mg/L
Adult	Less than 0.2 mg/dL	Less than 2 mg/L
Urine	0.03–0.37 mg/24 h	

DESCRIPTION & RATIONALE: β_2-Microglobulin is an amino acid peptide component of human leukocyte antigen (HLA) complexes. β_2-Microglobulin increases in inflammatory conditions and when lymphocyte turnover increases, such as in lymphocytic leukemia or when T-lymphocyte helper (OKT4) cells are attacked by human immunodeficiency virus

(HIV). Serum β_2-microglobulin becomes elevated with malfunctioning glomeruli, but decreases with malfunctioning tubules because it is metabolized by the renal tubules. Conversely, urine β_2-microglobulin decreases with malfunctioning glomeruli, but becomes elevated with malfunctioning tubules. ■

INDICATIONS:

- Detect aminoglycoside toxicity (becomes elevated before creatinine)
- Detect chronic lymphocytic leukemia, multiple myeloma, lung cancer, hepatoma, or breast cancer
- Detect HIV infection (*note:* levels do not correlate with stages of infection)
- Evaluate renal disease to differentiate glomerular from tubular dysfunction
- Monitor antiretroviral therapy

RESULT

Increased in:

- Acquired immunodeficiency syndrome (AIDS)
- Aminoglycoside toxicity
- Amyloidosis
- Autoimmune disorders
- Breast cancer
- Crohn's disease
- Felty's syndrome
- Hepatitis
- Hepatoma
- Hyperthyroidism
- Inflammation of all types
- Leukemia (chronic lymphocytic)
- Lung cancer
- Lymphoma
- Multiple myeloma
- Poisoning with heavy metals, such as mercury or cadmium
- Renal dialysis
- Renal disease (glomerular): serum only
- Renal disease (tubular): urine only
- Sarcoidosis
- Systemic lupus erythematosus
- Vasculitis
- Viral infections (e.g., cytomegalovirus)

Decreased in:

- Renal disease (glomerular): urine only
- Renal disease (tubular): serum only
- Response to zidovudine (AZT)

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs and proteins that may increase serum β_2-microglobulin levels include cefuroxime, cyclosporin A, gentamicin, interferon alfa, pentoxifylline, and tumor necrosis factor.
- Drugs that may decrease serum β_2-microglobulin levels include zidovudine.
- Drugs that may increase urine β_2-microglobulin levels include azathioprine, cisplatin, cyclosporin A, furosemide, gentamicin, mannitol, nifedipine, sisomicin, and tobramycin.
- Drugs that may decrease urine β_2-microglobulin levels include cilostazol.
- Urinary β_2-microglobulin is unstable at pH less than 5.5.
- Recent radioactive scans or radiation within 1 week before the test can interfere with test results when radioimmunoassay is the test method.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate renal disease, AIDS, and certain malignancies.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's genitourinary and immune system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Genitourinary and Immune System tables.
- Note any recent procedures that can interfere with test results.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so their effects can be taken into consideration when reviewing results.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Blood:

- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.

Urine:

- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device.
- Usually a 24-hour urine collection is ordered. Inform the patient that all urine over a 24-hour period must be saved; instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom as a reminder to save all urine.
- Instruct the patient to void all urine into the collection device and then pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

Intratest:

- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the venipuncture.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes or collection containers with the corresponding patient demographics, date, and time of collection.

Blood:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.

Urine:

- Obtain a clean 3-L urine specimen container, toilet-mounted collection

device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.

- If possible, begin the test between 6 and 8 a.m. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. At the same time the next morning, ask the patient to void and add this last voiding to the container.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection started.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection. If the specimen contains less than what was recorded as output, some urine may have been discarded, thus invalidating the test.

Blood or urine:

- Promptly transport the specimen to the laboratory for processing and analysis. Include on the urine specimen label the amount of urine and ingestion of any medications that can affect test results.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Educate the patient regarding the risk of infection related to immunosuppressed inflammatory response and fatigue related to decreased energy production.
- *Nutritional considerations:* Stress the importance of good nutrition, and suggest that the patient meet with a nutritional specialist. Also, stress the importance of following the care plan for medications and follow-up visits.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- *Social and cultural considerations:* Recognize anxiety related to test results, and be supportive of impaired activity related to weakness, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for AIDS information provided by the National Institutes of Health *(http://www.aidsinfo.nih.gov)*.
- *Social and cultural considerations:* Counsel the patient, as appropriate, regarding risk of transmission and proper prophylaxis, and reinforce the importance of strict adherence to the treatment regimen.
- *Social and cultural considerations:* Offer support, as appropriate, to patients who may be the victims of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nonthreatening atmosphere for a discussion during which risks of sexually transmitted diseases are explained. It is also important to discuss problems the patient may experience (e.g., guilt, depression, anger).

- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Inform the patient that retesting may be necessary. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include biopsy of the suspect tissue; CD4/CD8 enumeration; complete blood count; creatinine; erythrocyte sedimentation rate; gentamicin; hepatitis serology; HIV-1/HIV-2 serology; immunofixation electrophoresis; immunoglobulins A, G, and M; protein fraction electrophoresis; total protein; tobramycin; and urinalysis.

MUMPS SEROLOGY

SYNONYMS/ACRONYM: N/A.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Indirect immunofluorescence) Negative or less than a fourfold increase in titer.

DESCRIPTION & RATIONALE: Mumps serology is done to determine the presence of mumps antibody, indicating exposure to or active presence of mumps. Mumps, also known as *parotitis,* is an infectious viral disease of the parotid glands caused by a myxovirus that is transmitted by direct contact with or droplets spread from the saliva of an infected person. The incubation period averages 3 weeks. Virus can be shed in saliva for 2 weeks after infection and in urine for 2 weeks after the onset of symptoms. Complications of infection include aseptic meningitis, encephalitis, and inflammation of the testes, ovaries, and pancreas. The presence of immunoglobulin M (IgM) antibodies indicates acute infection. The presence of IgG antibodies indicates current or past infection. ■

INDICATIONS:

- Determine resistance to or protection against the mumps virus by a positive reaction, or susceptibility to mumps by a negative reaction
- Document immunity
- Evaluate mumps-like diseases and differentiate between these and actual mumps

Result

Positive findings in: Past or current mumps infection.

Critical values: N/A

Interfering factors: N/A

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to confirm acute infection with or immunity to the mumps virus.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly. Obtain a history of exposure.
- Obtain a history of the patient's immune system as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune System table.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm diagnosis. Any individual positive result should be repeated in 7 to 14 days to monitor a change in titer. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient in isolation precautions during the time of communicability or contagion.
- Emphasize that the patient must return to have a convalescent blood sample taken in 7 to 14 days.
- Inform the patient that the presence of mumps antibodies ensures lifelong immunity.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.

- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

MYOCARDIAL INFARCT SCAN

SYNONYMS/ACRONYM: PYP cardiac scan, infarct scan, pyrophosphate cardiac scan, acute myocardial infarction scan.

AREA OF APPLICATION: Heart, chest/thorax.

CONTRAST: Intravenous contrast medium.

DESCRIPTION & RATIONALE: Technetium-99m stannous pyrophosphate (PYP) scanning, also known as *myocardial infarct imaging,* reveals the presence of myocardial perfusion and the extent of myocardial infarction (MI). This procedure can distinguish new from old infarcts when a patient has had abnormal electrocardiograms (ECGs) and cardiac enzymes have returned to normal. PYP uptake by acutely infarcted tissue may be related to the influx of calcium through damaged cell membranes, which accompanies myocardial necrosis; that is, the radionuclide may be binding to calcium phosphates or to hydroxyapatite. The PYP in these damaged cells can be viewed as spots of increased radionuclide uptake that appear in 12 hours at the earliest.

PYP uptake usually takes place 24 to 72 hours after MI, and the radionuclide remains detectable for approximately 10 to 14 days after the MI. PYP uptake is proportional to the blood flow to the affected area; with large areas of necrosis, PYP uptake may be maximal around the periphery of a necrotic area, with little uptake being detectable in the poorly perfused center. Most of the PYP is concentrated in regions that have 20% to 40% of the normal blood flow.

Single-photon emission computed tomography (SPECT) can be used to visualize the heart from multiple angles and planes, enabling areas of

MI to be viewed with greater accuracy and resolution. This technique removes overlying structures that may confuse interpretation of the results. With the availability of assays of troponins, myocardial infarct imaging has become less important in the diagnosis of acute MI. ■

INDICATIONS:

- Aid in the diagnosis of (or confirm and locate) acute MI when ECG and enzyme testing do not provide a diagnosis
- Aid in the diagnosis of perioperative MI
- Differentiate between a new and old infarction
- Evaluate possible reinfarction or extension of the infarct
- Obtain baseline information about infarction before cardiac surgery

RESULT

Normal Findings:

- Normal coronary blood flow and tissue perfusion, with no PYP localization in the myocardium
- No uptake above background activity in the myocardium (*note:* when PYP uptake is present, it is graded in relation to adjacent rib activity)

Abnormal Findings:

- MI, indicated by increased PYP uptake in the myocardium

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risk of radiation exposure to the fetus
- Patients with hypersensitivity to the radionuclide

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Metallic objects within the examination field (e.g., jewelry, earrings, and/or dental amalgams), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Other nuclear scans done within the previous 24 to 48 hours
- Conditions such as chest wall trauma, cardiac trauma, or recent cardioversion procedure
- Myocarditis
- Pericarditis
- Left ventricular aneurysm
- Metastasis
- Valvular and coronary artery calcifications
- Cardiac neoplasms
- Aneurysms

Other considerations:

- Improper injection of the radionuclide may allow the tracer to seep deep into

the muscle tissue, producing erroneous hot spots.

- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiologic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Badges that reveal the level of exposure to radiation should be worn by persons working in the area where the examination is being done.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses blood flow to the heart.
- Obtain a history of the patient's complaints and symptoms, including a list of known allergens.
- Obtain a history of the patient's cardiovascular system, as well as results of previously performed laboratory tests, surgical procedures, and diagnostic procedures. For related diagnostic tests, refer to the Cardiovascular System table.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient's current medications.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Explain the purpose of the test and how the procedure is performed. Inform the patient that the procedure is performed in a nuclear medicine department, usually by a technologist and support staff, and takes approximately 30 to 60 minutes. Inform the patient that the technologist will administer an intravenous injection of the radionuclide and that he or she will need to return 2 to 3 hours later for the scan.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to fast for 4 hours, refrain from smoking for 4 to 6 hours, and withhold medications for 24 hours before the procedure.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.

Intratest:

- Ensure that the patient has complied with dietary and medication restrictions and other pretesting preparations. Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to lie very still during the procedure because movement will produce unclear images.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in a supine position on a flat table with foam wedges to help maintain position and immobilization.
- Wear gloves during the radionuclide injection and while handling the patient's urine.
- Imaging of the patient's heart begin

2 to 4 hours after injection of the radionuclide.

- Images of the heart are taken from a minimum of three angles: anterior, left anterior oblique, and left lateral. In most circumstances, however, SPECT is done so that the heart can be viewed from multiple angles and planes.
- The results are recorded on film or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume normal activity and diet, unless otherwise indicated.
- If the patient must return for additional imaging, advise the patient to rest in the interim and restrict diet to liquids before redistribution studies.
- Advise patient to drink increased amounts of fluids for 24 to 48 hours to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hours.
- Observe the injection site for redness, swelling, or hematoma.
- Observe patient for up to 60 minutes after the study for a possible anaphylactic reaction to the radionuclide, such as rash, tightening of throat, or difficulty breathing.
- Instruct the patient to flush the toilet immediately after each voiding following the procedure, and to wash hands meticulously with soap and water after each voiding for 24 hours after the procedure.
- Tell all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- If a woman who is breast-feeding must have a nuclear scan, she should not breast-feed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- No other radionuclide tests should be scheduled for 24 to 48 hours after this procedure.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the thorax, echocardiography, electrocardiogram, magnetic resonance imaging of the chest, and myocardial perfusion scan.

MYOCARDIAL PERFUSION HEART SCAN

SYNONYMS/ACRONYM: Thallium scan, sestamibi scan, stress thallium.

AREA OF APPLICATION: Heart, chest/thorax.

CONTRAST: Intravenous contrast medium.

DESCRIPTION & RATIONALE: Cardiac scanning is a nuclear medicine study that reveals clinical information about coronary blood flow, ventricular size, and cardiac function. Thallium-201 chloride rest or stress studies are used to evaluate myocardial blood flow to assist in diagnosing or determining the risk for ischemic cardiac disease, coronary artery disease (CAD), and myocardial infarction (MI). This procedure is an alternative to angiography or cardiac catheterization in cases in which these procedures may pose a risk to the patient. Thallium-201 is a potassium analogue and is taken up by myocardial cells proportional to blood flow to the cell and cell viability. During stress studies, the radionuclide is injected at peak exercise, after which the patient continues to exercise for several minutes. During exercise, areas of heart muscle supplied by normal arteries increase their blood supply, as well as the supply of thallium-201 delivery to the heart muscle, to a greater extent than regions of the heart muscle supplied by stenosed coronary arteries. This discrepancy in blood flow becomes apparent and quantifiable in subsequent imaging. Comparison of early stress images with images taken after 3 to 4 hours' redistribution (delayed images) enables differentiation between normally perfused, healthy myocardium (which is normal at rest but ischemic on stress) and infarcted myocardium.

Technetium-99m agents such as sestamibi (2-methoxyisobutylisonitrile) are delivered similarly to thallium-201 during myocardial perfusion imaging, but they are extracted to a lesser degree on the first pass through the heart and are taken up by the mitochondria. Over a short period, the radionuclide concentrates in the heart to the same degree as thallium-201. The advantage to technetium-99m agents is that immediate imaging is unnecessary because the radionuclide remains fixed to the heart muscle for several hours. The examination requires two separate injections, one for the rest portion and one for the stress portion of the procedure. These injections can take place on the same day or preferably over a 2-day period. Examination quality is improved if the patient is given a light, fatty meal after the radionuclide is

injected to facilitate hepatobiliary clearance of the radioactivity.

If stress testing cannot be performed by exercising, dipyridamole (Persantine) or adenosine, a vasodilator, can be administered orally or intravenously. A coronary vasodilator is administered before the thallium-201, or other radionuclide, and the scanning procedure is then performed. Vasodilators increase blood flow in normal coronary arteries twofold to threefold without exercise, and they reveal perfusion defects when blood flow is compromised by vessel pathology. Vasodilator-mediated myocardial perfusion scanning is reserved for patients who are unable to participate in treadmill, bicycle, or handgrip exercises for stress testing because of lung disease, neurologic disorders (e.g., multiple sclerosis, spinal cord injury), morbid obesity, and orthopedic disorders (e.g., arthritis, limb amputation).

Single-photon emission computed tomography can be used to visualize the heart from multiple angles and planes, enabling areas of MI to be viewed with greater accuracy and resolution. This technique removes overlying structures that may confuse interpretation of the results. ■

INDICATIONS:

- Aid in the diagnosis of CAD or risk for CAD
- Determine rest defects and reperfusion with delayed imaging in unstable angina
- Evaluate the extent of CAD and determine cardiac function
- Assess the function of collateral coronary arteries
- Evaluate bypass graft patency and general cardiac status after surgery
- Evaluate the site of an old MI to determine obstruction to cardiac muscle perfusion
- Evaluate the effectiveness of medication regimen and balloon angioplasty procedure on narrow coronary arteries

RESULT

Normal Findings:

- Normal wall motion, coronary blood flow, tissue perfusion, and ventricular size and function

Abnormal Findings:

- Abnormal stress and resting images, indicating previous MI
- Abnormal stress images with normal resting images, indicating transient ischemia
- Cardiac hypertrophy, indicated by increased radionuclide uptake in the myocardium
- Enlarged left ventricle
- Heart chamber disorder
- Ventricular septal defects

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who have taken sildenafil (Viagra) within the previous 48 hours, as this test may require the use of nitrates (nitroglycerin) that can precipitate life-threatening low blood pressure
- Patients with bleeding disorders
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risk of radiation exposure to the fetus
- Patients with hypersensitivity to the radionuclide

- Patients with left ventricular hypertrophy, right and left bundle branch block, or hypokalemia, and patients receiving cardiotonic therapy
- Patients with anginal pain at rest or patients with severe atherosclerotic coronary vessels, in whom dipyridamole testing cannot be performed
- Patients with asthma, because chemical stress with vasodilators can cause bronchospasms

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Medications such as digitalis and quinidine, which can alter cardiac contractility; and nitrates, which can affect cardiac performance
- Single-vessel disease, which can produce false-negative thallium-201 scanning results
- Conditions such as chest wall or cardiac trauma, angina that is difficult to control, significant cardiac arrhythmias, and recent cardioversion procedure
- Suboptimal cardiac stress or patient exhaustion preventing maximum heart rate testing
- Excessive eating or exercising between initial and redistribution imaging 4 hours later, which produces false-positive results
- Improper adjustment of the radiologic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images

Other considerations:

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- Inaccurate timing for imaging after radionuclide injection can affect the results.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses blood flow to the heart.
- Obtain a history of the patient's complaints and symptoms, including a list of known allergens.
- Obtain a history of the patient's cardiovascular system, as well as results of previously performed labo-

ratory tests, surgical procedures, and diagnostic procedures. For related laboratory tests, refer to the Cardiovascular System table.

- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Inform the patient that the procedure is performed in a special department, usually in a radiology or vascular suite, by a health care practitioner and support staff, and takes approximately 30 to 60 minutes.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an intravenous (IV) line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- Instruct the patient to fast for 4 hours, refrain from smoking for 4 to 6 hours, and withhold medications for 24 hours before the test. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.
- Instruct the patient to wear walking shoes (if treadmill exercise testing is to be performed), and emphasize the importance of the patient reporting fatigue, pain, or shortness of breath.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*
- This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.

Intratest:

- Ensure that the patient has complied with dietary and medication restrictions and other pretesting preparations. Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Record baseline vital signs and assess neurologic status. Protocols may vary from facility to facility.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Establish IV fluid line for the injection of emergency drugs and of sedatives.
- Place electrocardiographic (ECG) electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has

ventricular arrhythmias. Monitor the patient's blood pressure throughout the procedure by using an automated blood pressure machine.

- Assist the patient onto the treadmill or bicycle ergometer and ask the patient to exercise to a calculated 80% to 85% of the maximum heart rate, as determined by the protocol selected.
- Wear gloves during the radionuclide injection and while handling the patient's urine.
- Thallium-201 is injected 60 to 90 seconds before exercise is terminated, and imaging is done immediately in the supine position and repeated in 4 hours.
- Patients who cannot exercise are given dipyridamole 4 minutes before thallium-201 is injected.
- Inform the patient that movement during the resting procedure affects the results and makes interpretation difficult.
- The results are recorded on film or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the health care practitioner. If the patient must return for further thallium-201 imaging, advise the patient to rest in the interim and to restrict diet to liquids before redistribution studies.
- Monitor vital signs and ECG tracings every 15 minutes for 60 minutes after the procedure. Compare with baseline values. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching or decreased urinary output.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to drink increased amounts of fluids for 24 to 48 hours to eliminate the radionuclide from the body, unless contraindicated. Educate the patient that radionuclide is eliminated from the body within 6 to 24 hours.
- Instruct the patient to flush the toilet immediately after each voiding following the procedure, and to wash hands meticulously with soap and water after each voiding for 24 hours after the procedure.
- Instruct all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- If a woman who is breast-feeding must have a nuclear scan, she should not breast-feed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- *Nutritional considerations:* A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.
- No other radionuclide tests should be scheduled for 24 to 48 hours after this procedure.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information

regarding the clinical implications of the test results, as appropriate.

- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the thorax, echocardiogram, electrocardiography, Holter monitoring, and magnetic resonance imaging of the chest.

MYOGLOBIN

SYNONYM/ACRONYM: MB.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Nephelometry)

Conventional & SI Units
5–70 μg/dL

DESCRIPTION & RATIONALE: Myoglobin is an oxygen-binding muscle protein normally found in skeletal and cardiac muscle. It is released into the bloodstream after muscle damage from ischemia, trauma, or inflammation. Although myoglobin testing is more sensitive than creatinine kinase and isoenzymes, it does not indicate the specific site involved. ■

INDICATIONS:

- Assist in predicting a flare-up of polymyositis
- Estimate damage from skeletal muscle injury or myocardial infarction

RESULT

Increased in:

- Cardiac surgery
- Cocaine use

- Exercise
- Malignant hyperthermia
- Myocardial infarction
- Progressive muscular dystrophy
- Renal failure
- Rhabdomyolysis
- Shock
- Thrombolytic therapy

Decreased in:

- Myasthenia gravis
- Presence of antibodies to myoglobin, as seen in patients with polymyositis
- Rheumatoid arthritis

CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the diagnosis of skeletal or myocardial muscle damage.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular and musculoskeletal system as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Cardiovascular and Musculoskeletal System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold

pressure bandage in place, or replace with a plastic bandage.

- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include antiarrhythmic drugs, apolipoprotein A, apolipoprotein B, aspartate aminotransferase, atrial natriuretic peptide, blood gases, B-type natriuretic peptide, calcium (blood and ionized), cholesterol (total, HDL, and LDL), C-reactive protein, creatine kinase and isoenzymes, glucose, glycated hemoglobin, homocysteine, ketones, lactate dehydrogenase and isoenzymes, lipoprotein electrophoresis, magnesium, pericardial fluid, potassium, triglycerides, and troponin.

NERVE FIBER ANALYSIS

SYNONYMS/ACRONYMS: NFA.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION & RATIONALE: There are over 1 million ganglion nerve cells in the retina of each eye. Each nerve cell has a long fiber that travels through the nerve fiber layer of the retina and exits the eye through the optic nerve. The optic nerve is made up of all the ganglion nerve fibers and connects the eye to the brain for vision to occur. As the ganglion cells die, the nerve fiber layer becomes thinner and an empty space in the optic nerve, called the cup, becomes larger. The thinning of the nerve fiber layer and the enlargement of the nerve fiber cup are measurements used to gauge the extent of damage to the retina. Significant damage to the nerve fiber layer occurs before loss of vision is noticed by the patient. Damage can be caused by glaucoma or by aging or occlusion of the vessels in the retina. Ganglion cell loss due to glaucoma begins in the periphery of the retina, thereby first affecting

peripheral vision. This change in vision can also be detected by visual field testing. There are several different techniques for measuring nerve fiber layer thickness. One of the most common employs the use of a laser that emits polarizing light waves. The laser's computer measures the change in direction of alignment of the light beam after it passes through the nerve fiber layer tissue. The amount of change in polarization correlates to the thickness of the retinal nerve fiber layer. ■

INDICATIONS:

- Assist in the diagnosis of eye diseases
- Determine retinal nerve fiber layer thickness
- Monitor the effects of various therapies or the progression of conditions resulting in loss of vision

RESULT

Normal Findings:

- Normal nerve fiber layer thickness

Abnormal Findings:

- Glaucoma or suspicion of glaucoma
- Ocular hypertension

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair the results of the examination:

- Inability of the patient to fixate on focal point
- Corneal disorder that prevents proper alignment of the retinal nerve fibers
- Dense cataract that prevents visualization of a clear nerve fiber image
- Inability of the patient to cooperate or remain still during the test because of age, significant pain, or mental status

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure measures the thickness of the retinal nerve fiber layer.
- Obtain a history of the patient's complaints, including a list of known allergens.
- Obtain a history of narrow-angle glaucoma. Obtain a history of known or suspected visual impairment, changes in visual acuity, and use of glasses or contact lenses.
- Obtain a history of the patient's known or suspected vision loss, including type and cause; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit. For related diagnostic tests, refer to the table of tests associated with the Ocular System.
- Obtain a history of results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.
- Review the procedure with the patient. Explain that the patient will be requested to fixate the eyes during the procedure. Address concerns about pain related to the procedure. Explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Explain to the patient that some discomfort may be experienced after the test when the numbness wears

off from anesthetic drops administered prior to the test. Inform the patient that a technician, optometrist, or physician performs the test, and that to evaluate both eyes, the test can take 10 to 15 minutes.

- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- Seat the patient comfortably. Instruct the patient to look straight ahead, keeping the eyes open and unblinking.
- Instill topical anesthetic in each eye, as ordered, and allow time for it to work. Topical anesthetic drops are placed in the eye with the patient looking up and the solution directed at the six o'clock position of the sclera (white of the eye) near the limbus (grey, semitransparent area of the eyeball where the cornea and sclera meet). The dropper bottle should not touch the eyelashes.
- The equipment used to perform the test determines whether dilation of the pupils is required (OCT) or avoided (GDX).
- Request that the patient look straight ahead at a fixation light with the chin in the chin rest and forehead against the support bar. The patient should be reminded not to move the eyes or blink the eyelids as the measurement is taken. The person performing the test can store baseline data or retrieve previous images from the equipment. The equipment can create the mean image from current and previous data, and its computer can make a comparison against previous images.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss or perceived loss of driving privileges. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Instruct the patient in the use of any ordered medications, usually eyedrops. Explain the importance of adhering to the therapy regimen, especially since glaucoma does not present symptoms. Instruct the patient in both the ocular side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include fundus photography, gonioscopy, pachymetry, slit-lamp biomicroscopy, and visual field testing.

OSMOLALITY, BLOOD AND URINE

SYNONYM/ACRONYM: Osmo.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube; urine (5 mL) from an unpreserved random specimen collected in a clean plastic collection container.

REFERENCE VALUE: (Method: Freezing point depression)

	Conventional Units	SI Units (Conventional Units × 1)
Serum	275–295 mOsm/kg	275–295 mmol/kg
Urine		
Newborn	75–300 mOsm/kg	75–300 mmol/kg
Children and adults	250–900 mOsm/kg	250–900 mmol/kg

DESCRIPTION & RATIONALE: Osmolality refers to the number of particles in solution; it is independent of particle size, shape, and charge. Measurement of osmotic concentration in serum provides clinically useful information about water and dissolved-particle transport across fluid compartment membranes. Osmolality is used to assist in the diagnosis of metabolic, renal, and endocrine disorders. The simultaneous determination of serum and urine osmolality provides the opportunity to compare values between the two fluids. A normal urine-to-serum ratio is approximately 0.2 to 4.7 for random samples and greater than 3.0 for first-morning samples (dehydration normally occurs overnight). The major dissolved particles that contribute to osmolality are sodium, chloride, bicarbonate, urea, and glucose. Some of these substances are used in the following calculated estimate:

$$\text{Serum osmolality} = \{[2\ (Na^{+})] + [\text{glucose}/18] + [\text{BUN}/2.8]\}$$

Measured osmolality is higher than the estimated value. The osmolal gap is the difference between the measured and calculated values and is normally 5 to 10 mOsm/kg. If the difference is greater than 15 mOsm/kg, consider ethylene glycol, isopropanol, methanol, or ethanol toxicity. These substances behave like antifreeze, lowering the freezing point in the blood, and provide misleadingly high results. ■

Indications

Serum:

- Assist in the evaluation of antidiuretic hormone (ADH) function
- Assist in rapid screening for toxic substances, such as ethylene glycol, ethanol, isopropanol, and methanol
- Evaluate electrolyte and acid-base balance
- Evaluate state of hydration

Urine:

- Evaluate concentrating ability of the kidneys
- Evaluate diabetes insipidus
- Evaluate neonatal patients with protein or glucose in the urine
- Perform workup for renal disease

Result

Increased in:

- Serum:
  Azotemia
  Dehydration
  Diabetes insipidus
  Diabetic ketoacidosis
  Hypercalcemia
  Hypernatremia
- Urine:
  Amyloidosis
  Azotemia
  Congestive heart failure
  Dehydration
  Hyponatremia
  Syndrome of inappropriate antidiuretic hormone production (SIADH)

Decreased in:

- Serum:
  Adrenocorticoid insufficiency
  Hyponatremia
  SIADH
  Water intoxication
- Urine:
  Diabetes insipidus
  Hypernatremia
  Hypokalemia
  Primary polydipsia

Critical Values:

Serum:
Less than 265 mOsm/kg
Greater than 320 mOsm/kg

Note and immediately report to the health care practitioner any critically increased or decreased values and related symptoms.

Serious clinical conditions may be associated with elevated or decreased serum osmolality. The following conditions are associated with elevated serum osmolality:

Respiratory arrest: 360 mOsm/kg
Stupor of hyperglycemia: 385 mOsm/kg
Grand mal seizures: 420 mOsm/kg
Death: greater than 420 mOsm/kg

Symptoms of critically high levels include poor skin turgor, listlessness, acidosis (decreased pH), shock, seizures, coma, and cardiopulmonary arrest. Intervention may include close monitoring of electrolytes, administering intravenous fluids with the appropriate composition to shift water either into or out of the intravascular space as needed, monitoring cardiac signs, continuing neurologic checks, and taking seizure precautions.

Interfering Factors:

- Drugs that may increase serum osmolality include citrates (as an anticoagulant), corticosteroids, ethylene glycol, glycerin, inulin, ioxithalamic acid, mannitol, and methoxyflurane.
- Drugs that may decrease serum osmolality include bendroflumethiazide, carbamazepine, chlorpromazine, chlorthalidone, cyclophosphamide, cyclothiazide, hydrochlorothiazide, lorcainide, methyclothiazide, and polythiazide.

- Drugs that may increase urine osmolality include anesthetic agents, chlorpropamide, cyclophosphamide, furosemide, mannitol, metolazone, octreotide, phloridzin, and vincristine.
- Drugs that may decrease urine osmolality include captopril, demeclocycline, glyburide, lithium, methoxyflurane, octreotide, tolazamide, and verapamil.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate electrolyte and water balance.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine and genitourinary systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine and Genitourinary System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that blood specimen collection takes approximately 5 to 10 minutes; random urine collection takes approximately 5 minutes and depends on the cooperation of the patient. Urine specimen collection may also be timed. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture; there will be no discomfort during urine collection.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Direct the patient to breathe normally and to avoid unnecessary movement during the venipuncture.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes or collection containers with the corresponding patient demographics, date, and time of collection.

Blood:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.

Urine:

- Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device.
- Either a random specimen or a timed collection may be requested. For timed specimens, a 12- or 24-hour time frame for urine collection may be ordered. Inform the patient that all urine must be saved during that 12 or 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.

- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

Clean-catch specimen:

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling catheter:

- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 minutes before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Blood or urine:

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Decreased osmolality may be associated with overhydration. Observe the patient for signs and symptoms of fluid-volume excess related to excess electrolyte intake, fluid-volume deficit related to active loss, or risk of injury related to an alteration in body chemistry. (For electrolyte-specific dietary references, see monographs titled "Chloride," "Potassium," and "Sodium.")
- Increased osmolality may be associated with dehydration. Evaluate the patient for signs and symptoms of dehydration. Dehydration is a significant and common finding in geriatric and other patients in whom renal function has deteriorated.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the National Kidney Foundation *(http://www.kidney.org).*
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include antidiuretic hormone, ammonia, blood and urine urea nitrogen, blood and urine creatinine, blood and urine electrolytes, ethanol, glucose, and blood and urine ketones.

OSMOTIC FRAGILITY

SYNONYM/ACRONYM: Red blood cell osmotic fragility, OF.

SPECIMEN: Whole blood (1 mL) collected in a green-top (heparin) tube and two peripheral blood smears.

REFERENCE VALUE: (Method: Spectrophotometry) Hemolysis begins at 0.5 w/v sodium chloride (NaCl) solution and is complete at 0.3 w/v NaCl solution. Results are compared to a normal curve.

DESCRIPTION & RATIONALE: Osmotic fragility (OF) is an indication of the ability of red blood cells (RBCs) to take on water without lysing. In this test, RBCs are placed in graded dilutions of sodium chloride. Swelling of the cells occurs at lower concentrations of NaCl as they take on water in the hypotonic solution. Thicker cells, such as spherocytes, have an increased OF; thinner cells have a decreased OF. ■

INDICATIONS: Evaluate hemolytic anemia

RESULT

Increased in:

- Acquired immune hemolytic anemias
- Hemolytic disease of the newborn
- Hereditary spherocytosis
- Malaria
- Pyruvate kinase deficiency

Decreased in:

- Asplenia
- Hemoglobinopathies
- Iron-deficiency anemia
- Liver disease
- Reticulocytosis
- Thalassemias

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase osmotic fragility include dapsone.
- Parasitic infestations, such as malaria, may independently cause cell hemolysis.
- Specimens should be submitted for analysis immediately after collection.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to assist in the diagnosis of hereditary spherocytosis.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the

appropriate health care practitioner accordingly.

- Obtain a history of the patient's hematopoietic system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic System table.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL green-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include complete blood count, glucose-6-phosphate dehydrogenase, Ham's test, hemoglobin electrophoresis, total iron, pyruvate kinase, and red blood cell morphology and inclusions.

OSTEOCALCIN

SYNONYMS/ACRONYMS: Bone GLA protein, BGP.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Radioimmunoassay)

Age and Sex	Conventional Units	SI Units (Conventional Units × 1)
Newborn	20–40 ng/mL	20–40 μg/L
1–17 y	2.8–41 ng/mL	2.8–41 μg/L
Adult		
Male	3–13 ng/mL	3–13 μg/L
Female		
Premenopausal	0.4–8.2 ng/mL	0.4–8.2 μg/L
Postmenopausal	1.5–11 ng/mL	1.5–11 μg/L

DESCRIPTION & RATIONALE: Osteocalcin is an important bone cell matrix protein and a sensitive marker in bone metabolism. It is produced by osteoblasts during the matrix mineralization phase of bone formation and is the most abundant noncollagenous bone cell protein. Synthesis of osteocalcin is dependent on vitamin K. Osteocalcin levels parallel alkaline phosphatase levels. Osteocalcin levels are affected by a number of factors, including the hormone estrogen. Assessment of osteocalcin levels permits indirect measurement of osteoblast activity and bone formation. Because it is released into the bloodstream during bone resorption, there is some question as to whether osteocalcin might also be considered a marker for bone matrix degradation and turnover. ■

INDICATIONS:

- Assist in the diagnosis of bone cancer
- Evaluate bone disease
- Evaluate bone metabolism
- Monitor effectiveness of estrogen replacement therapy

RESULT

Increased in:

- Adolescents undergoing a growth spurt
- Chronic renal failure
- Hyperthyroidism (primary and secondary)
- Metastatic skeletal disease

- Paget's disease
- Renal osteodystrophy
- Some patients with osteoporosis

Decreased in:

- Growth hormone deficiency
- Pregnancy
- Primary biliary cirrhosis

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase calcitonin levels include anticonvulsants, calcitriol, and estrogens.
- Drugs that may decrease calcitonin levels include glucocorticoids.
- Recent radioactive scans or radiation within 1 week before the serum osteocalcin test can interfere with test results when radioimmunoassay is the test method.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate bone disease.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's musculoskeletal system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Musculoskeletal System table.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.

- *Nutritional considerations:* Increased osteocalcin levels may be associated with skeletal disease. Nutritional therapy is indicated for individuals identified as being at high risk for developing osteoporosis. Educate the patient regarding the National Osteoporosis Foundation's guidelines, which include a regular regimen of weight-bearing exercises, limited alcohol intake, avoidance of tobacco products, and adequate dietary intake of vitamin D (400 to 800 IU/day) and calcium (120 mg/day). Dietary calcium can be obtained from animal or plant sources. Milk and milk products, sardines, clams, oysters, salmon, rhubarb, spinach, beet greens, broccoli, kale, tofu, legumes, and fortified orange juice are high in calcium. Milk and milk products also contain vitamin D and lactose, which assist calcium absorption. Cooked vegetables yield more absorbable calcium than raw vegetables. Patients should be informed of the substances that can inhibit calcium absorption by irreversibly binding to some of the calcium, making it unavailable for absorption, such as oxalates, which naturally occur in some vegetables; phytic acid, found in some cereals; and insoluble dietary fiber (in excessive amounts). Excessive protein intake can also negatively affect calcium absorption, especially if it is combined with foods high in phosphorus. Vitamin D is synthesized by the skin and is also available in fortified dairy foods and cod liver oil.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include alkaline phosphatase, calcium (blood and urine), collagen cross-linked N-telopeptide, parathyroid hormone, phosphorus, and vitamin D.

OTOSCOPY

SYNONYMS/ACRONYMS: N/A.

AREA OF APPLICATION: Ears.

CONTRAST: N/A.

DESCRIPTION & RATIONALE: This noninvasive procedure is used to inspect the external ear, auditory canal, and tympanic membrane. Otoscopy is an essential part of any general physical examination, but is also done before any other audiologic studies when symptoms of ear pain or hearing loss are present. ■

INDICATIONS:

- Detect causes of deafness, obstruction, stenosis, or swelling of the pinna or canal causing a narrowing or closure that prevents sound from entering
- Detect ear abnormalities during routine physical examination
- Diagnose cause of ear pain
- Remove impacted cerumen (with a dull ring curette) or foreign bodies (with a forceps) that are obstructing the entrance of sound waves into the ear
- Evaluate acute or chronic otitis media and effectiveness of therapy in controlling infections

RESULT

Normal Findings:

- Normal structure and appearance of the external ear, auditory canal, and tympanic membrane.

  Pinna: funnel-shaped cartilaginous structure; no evidence of infection, pain, dermatitis with swelling, redness, or itching

  External auditory canal: S-shaped canal lined with fine hairs, sebaceous and ceruminous glands; no evidence of redness, lesions, edema, scaliness, pain, accumulation of cerumen, drainage, or presence of foreign bodies

  Tympanic membrane: shallow, circular cone that is shiny and pearl gray in color, semitransparent whitish cord crossing from front to back just under the upper edge, cone of light on the right side at the 4 o'clock position; no evidence of bulging, retraction, lusterless membrane, or obliteration of the cone of light

Abnormal Findings:

- Cerumen accumulation
- Ear trauma
- Foreign bodies
- Otitis externa
- Otitis media
- Tympanic membrane perforation or rupture

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair the results of the examination:

- Obstruction of the auditory canal with cerumen, dried drainage, or foreign bodies that prevent introduction of the otoscope

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure is performed to investigate suspected ear disorders.
- Obtain a history of the patient's complaints, including a list of known allergens.
- Obtain a history of the patient's known or suspected hearing loss, including type and cause; ear conditions with treatment regimens; ear surgery; and other tests and procedures to assess and diagnose auditory deficit. Obtain a history of the patient's complaints of pain, itching, drainage, deafness, or presence of tympanotomy tube.

- Obtain a history of results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures.
- Obtain a list of the medications the patient is taking, especially antibiotic regimen, as well as herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the caregiver that he or she may need to restrain a child in order to prevent damage to the ear if the child cannot remain still. Address concerns about pain related to the procedure. Explain to the patient that no discomfort will be experienced during the test. Inform the patient that a physician, nurse or health care practitioner specializing in this field performs the test, and that to evaluate both ears, the test can take 5 to 10 minutes.
- Ensure that the external auditory canal is clear of impacted cerumen.

Intratest:

- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- Administer ear drops or irrigation to prepare for cerumen removal, if ordered.
- Place adult patient in a sitting position; place a child in a supine position on the caregiver's lap. Request that the patient remain very still during the examination; a child can be restrained by the caregiver if needed.
- Assemble the otoscope with the correct-size speculum to fit the size of the patient's ear and check the light source. For the adult, tilt the head slightly away and, with the nondominant hand, pull the pinna upward and backward. For a child, hold the head steady or have the caregiver hold the child's head steady, depending on the age, and pull the pinna downward. Gently and slowly insert the speculum into the ear canal downward and forward with the handle of the otoscope held downward. For the child, hold the handle upward while placing the edge of the hand holding the otoscope on the head to steady it during insertion. If the speculum resists insertion, withdraw and attach a smaller one.
- Place an eye to the lens of the otoscope, turn on the light source, and advance the speculum into the ear canal until the tympanic membrane is visible. Examine the posterior and anterior membrane, cone of light, outer rim (annulus), umbo, handle of the malleus, folds, and pars tensa.
- Culture any effusion with a sterile swab and culture tube (see "Culture, Bacterial, Ear," monograph); or a health care practitioner will perform needle aspiration from the middle ear through the tympanic membrane during the examination. Other procedures such as cerumen and foreign body removal can also be performed.
- Pneumatic otoscopy can be done to determine tympanic membrane flexibility. This test permits the introduction of air into the canal that reveals a reduction in movement of the membrane in otitis media and absence of movement in chronic otitis media.
- The results are recorded manually for recall and postprocedure interpretation by a health care professional specializing in this field.

Post-test:

- Administer ear drops of a soothing oil, and as ordered, if the canal is irritated by removal of cerumen or foreign bodies.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test

results, and be supportive of impaired activity related to hearing loss. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include audiometry and bacterial culture of the ear.

OVA AND PARASITES, STOOL

SYNONYM/ACRONYM: O & P.

SPECIMEN: Stool collected in a clean plastic, tightly capped container.

REFERENCE VALUE: (Method: Macroscopic and microscopic examination)
No presence of parasites, ova, or larvae.

DESCRIPTION & RATIONALE: This test evaluates stool for the presence of intestinal parasites and their eggs. Some parasites are nonpathogenic; others, such as protozoa and worms, can cause serious illness. ■

INDICATIONS: Assist in the diagnosis of parasitic infestation

RESULT

Positive findings in:

- Amebiasis—*Entamoeba histolytica* infection
- Ascariasis—*Ascaris lumbricoides* infection
- Blastocystis—*Blastocystis hominis* infection
- Cryptosporidiosis—*Cryptosporidium parvum* infection
- Enterobiasis—*Enterobius vermicularis* (pinworm) infection
- Giardiasis—*Giardia lamblia* infection
- Hookworm disease—*Ancylostoma duodenale, Necator americanus* infection
- Isospora—*Isospora belli* infection
- Schistosomiasis—*Schistosoma haematobium, Schistosoma japonicum, Schistosoma mansoni* infection
- Strongyloidiasis—*Strongyloides stercoralis* infection

- Tapeworm disease—*Diphyllobothrium, Hymenolepiasis, Taenia saginata, Taenia solium* infection
- Trematode disease—*Clonorchis sinensis, Fasciola hepatica, Fasciolopsis buski* infection
- Trichuriasis—*Trichuris trichiura* infection

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Failure to test a fresh specimen may yield a false-negative result.
- Antimicrobial or antiamebic therapy within 10 days of test may yield a false-negative result.
- Failure to wait 1 week after a gastrointestinal study using barium or after laxative use can affect test results.
- Medications such as antacids, antibiotics, antidiarrheal compounds, bismuth, castor oil, iron, magnesia, or psyllium fiber (Metamucil) may interfere with analysis.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the diagnosis of parasitic infection.
- Obtain a history of the patient's complaints, including a list of known allergens, and inform the appropriate health care practitioner accordingly. Document any travel to foreign countries.
- Obtain a history of the patient's gastrointestinal and immune systems, and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Gastrointestinal and Immune System tables.
- Note any recent therapies that can interfere with test results.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Instruct the patient on handwashing procedures, and inform the patient that the infection may be contagious. Warn the patient not to contaminate the specimen with urine, toilet paper, or toilet water. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to avoid medications that interfere with test results.
- There are no food or fluid restrictions, unless by medical direction.

Intratest:

- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.
- Collect a stool specimen directly into the container. If the patient is bedridden, use a clean bedpan and transfer the specimen into the container using a tongue depressor.
- Specimens to be examined for the presence of pinworms are collected by the "Scotch tape" method in the morning before bathing or defecation. A small paddle with a piece of cellophane tape (sticky side facing out) is pressed against the perianal area. The tape is placed in a collection container and submitted to

determine if ova are present. Sometimes adult worms are observed protruding from the rectum.

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Educate the patient with positive findings on the transmission of the parasite, as indicated. Warn the patient that one negative result does not rule out parasitic infestation and that additional specimens may be required. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include fecal analysis, immunoglobulin E, and stool culture.

OXALATE, URINE

SYNONYM/ACRONYM: N/A.

SPECIMEN: Urine (25 mL) from a timed specimen collected in a clean plastic collection container with hydrogen chloride (HCl) as a preservative.

REFERENCE VALUE: (Method: Spectrophotometry)

Conventional Units	SI Units (Conventional Units × 11.4)
0–40 mg/24 h	0–456 μmol/24 h

DESCRIPTION & RATIONALE: Oxalate is derived from the metabolism of oxalic acid, glycine, and ascorbic acid. Some individuals with malabsorption disorders absorb and excrete abnormally high amounts of oxalate, resulting in *hyperoxaluria.* Hyperoxaluria may be seen in patients who consume large amounts of animal protein, certain fruits and vegetables, or megadoses of vitamin C (ascorbic acid). Hyperoxaluria is also associated with ethylene glycol poisoning (oxalic acid is used in cleaning and bleaching agents). Patients who absorb and excrete large amounts of oxalate may form calcium oxalate kidney stones. Simultaneous measurement of serum and urine calcium is often requested. ■

INDICATIONS:

- Assist in the evaluation of patients with ethylene glycol poisoning
- Assist in the evaluation of patients with a history of kidney stones
- Assist in the evaluation of patients with malabsorption syndromes or patients who have had jejunoileal bypass surgery

RESULT

Increased in:

- Bacterial overgrowth
- Biliary tract disease
- Bowel disease
- Celiac disease
- Cirrhosis
- Crohn's disease
- Diabetes
- Ethylene glycol poisoning
- Ileal resection
- Jejunal shunt
- Pancreatic disease
- Primary hereditary hyperoxaluria (rare)
- Pyridoxine (vitamin B_6) deficiency
- Sarcoidosis

Decreased in:

- Hypercalciuria
- Renal failure

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs and vitamins that may increase oxalate levels include methoxyflurane, ascorbic acid, and calcium.
- Drugs that may decrease oxalate levels include nifedipine and pyridoxine.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to identify patients at risk for renal calculus formation, specifically calcium oxalate calculi. Hyperoxaluria is also commonly observed in patients with malabsorption conditions.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal and genitourinary systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Gastrointestinal and Genitourinary System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements and nutraceuticals. The requesting health care

practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.

- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
- Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no fluid or medication restrictions, unless by medical direction.
- Calcium supplements, gelatin, rhubarb, spinach, strawberries, tomatoes, and vitamin C should be restricted for at least 24 hours before the test. High-protein meals should also be avoided 24 hours before specimen collection.

Intratest:

- Ensure that the patient has complied with dietary restrictions; assure that restricted foods have been avoided for at least 24 hours prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection.

Random specimen (collect in early morning):

Clean-catch specimen:

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling catheter:

- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 minutes before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Timed specimen:

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m.,

if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container.

- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container's label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.

General:

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, as directed by the health care practitioner.
- *Nutritional considerations:* Consideration may be given to lessening dietary intake of oxalate if urine levels are increased. Encourage patients with abnormal results to seek advice regarding dietary modifications from a trained nutritionist. Magnesium supplementation may be recommended for patients with gastrointestinal disease to prevent the development of calcium oxalate kidney stones.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include serum and urine calcium, kidney stone analysis, serum and urine magnesium, urinalysis, urine uric acid, and vitamin C.

PACHYMETRY

SYNONYMS/ACRONYMS: N/A.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION & RATIONALE: Pachymetry is the measurement of the thickness of the cornea using an ultrasound device called a pachymeter. Refractive surgery procedures such as LASIK remove tissue from the cornea. Pachymetry is used to ensure that there will be enough central corneal tissue remaining after surgery to prevent ectasia, or abnormal bowing, of thin corneas. Also, recently published ophthalmology studies point to a correlation between increased risk of glaucoma and decreased corneal thickness. This correlation has influenced some health care practitioners to include pachymetry as a part of a regular eye health examination for patients who have a family history of glaucoma or who are part of a high-risk population. African Americans have a higher incidence of glaucoma than any other ethnic group. ■

INDICATIONS:

- Assist in the diagnosis of glaucoma (*note:* the intraocular pressure in glaucoma patients with a thin cornea, 530 μ or less, may be higher than in patients whose corneal thickness is within normal limits)
- Determine corneal thickness in potential refractive surgery candidates
- Monitor the effects of various therapies using eyedrops, laser, or filtering surgery

RESULT

Normal Findings:

- 535 to 555 μ

Abnormal Findings:

- Bullous keratopathy
- Corneal rejection after penetrating keratoplasty
- Fuchs endothelial dystrophy
- Glaucoma

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair the results of the examination:

- Inability of the patient to cooperate or remain still during the test because of age, significant pain, or mental status
- Improper technique during application of the probe tip to the cornea

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure measures corneal thickness.
- Obtain a history of the patient's complaints, including a list of known allergens.
- Obtain a history of narrow-angle glaucoma. Obtain a history of known or suspected visual impairment, changes in visual acuity, use of glasses or contact lenses.
- Obtain a history of the patient's known or suspected vision loss, including type and cause; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit. For related diagnostic tests, refer to the table of tests associated with the Ocular System.
- Obtain a history of results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.
- Review the procedure with the patient. Explain that the patient will be requested to fixate the eyes during the procedure. Address concerns about pain related to the procedure. Explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Explain to the patient that some discomfort may be experienced after the test when the numbness wears off from anesthetic drops administered prior to the test, or discomfort may occur if too much pressure is used during the test. Inform the patient that a technician, optometrist, or physician performs the test, and that to evaluate both eyes, the test can take 3 to 5 minutes.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- Seat the patient comfortably. Instruct the patient to look straight ahead, keeping the eyes open and unblinking.
- Instill topical anesthetic in each eye, as ordered, and allow time for it to work. Topical anesthetic drops are placed in the eye with the patient looking up and the solution directed at the six o'clock position of the sclera (white of the eye) near the limbus (grey, semitransparent area of the eyeball where the cornea and sclera meet). The dropper bottle should not touch the eyelashes.
- Request that the patient look straight ahead while the probe of the pachymeter is applied directly on the cornea of the eye. Take an average of three readings for each eye. Individual readings should be within 10 μ. Results on both eyes should be similar.
- The results are recorded manually for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.

- Recognize anxiety related to test results. Encourage the family to recognize and be supportive of impaired activity related to vision loss, perceived loss of driving privileges, or the possibility of requiring corrective lenses (self-image). Discuss the implications of test results on the patient's lifestyle. Reassure the patient regarding concerns related to their impending cataract surgery. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include fundus photography, gonioscopy, intraocular pressure, and visual field testing.

PAPANICOLAOU SMEAR

SYNONYMS/ACRONYM: Pap smear, cervical smear.

SPECIMEN: Cervical and endocervical cells.

REFERENCE VALUE: (Method: Microscopic examination of fixed and stained smear) Reporting of Pap smear findings may follow one of several formats and may vary from laboratory to laboratory. Simplified content of the two most common formats for interpretation are listed in the table.

Bethesda System	Description
Specimen type	Conventional, liquid based or other
Specimen adequacy	*Satisfactory* for evaluation—(endocervical/transformation zone component is described as present/absent along with other quality indicators, e.g., partially obscuring blood, inflammation) *Unsatisfactory* for evaluation—either the specimen is rejected and the reason given or the specimen is processed and examined but not evaluated for epithelial abnormalities and the reason is given

(*Continued on the following page*)

Bethesda System	Description
General categorization	*Negative* for intraepithelial lesion or malignancy *Epithelial cell abnormality* (abnormality is specified in the interpretation section of the report) *Other comments*
Automated review	Indicates the case was examined by an automated device and the results are listed along with the name of the device
Ancillary testing	Describes the test method and result
Interpretation/result	Organisms—*Trichomonas vaginalis*, fungal organisms consistent with *Candida* spp., shift in flora suggestive of bacterial vaginosis, bacteria morphologically consistent with *Actinomyces* spp., cellular changes consistent with Herpes simplex virus *Other nonneoplastic findings*—reactive cellular changes associated with inflammation, radiation, intrauterine device; glandular cell status post-hysterectomy; atrophy; endometrial cells (in a woman of 40 years or greater)
Epithelial cell abnormalities	*Squamous cell* *Atypical squamous cells*—of undetermined significance (ASC-US) -cannot exclude HSIL (ASC-H) *Low grade squamous intraepithelial lesion (LSIL)*—encompassing: HPV/mild dysplasia/ CIN 1 *High grade squamous intraepithelial lesion (HSIL)*—encompassing: moderate and severe dysplasia, CIS/CIN 2 and CIN 3 –with features suspicious for invasion (if invasion is suspected) *Squamous cell carcinoma* *Glandular cell* Atypical—endocervical cells (NOS or specify otherwise) –endometrial cells (NOS or specify otherwise) –glandular cells (NOS or specify otherwise) Atypical—endocervical cells, favor neoplastic –glandular cells – favor neoplastic Endocervical carcinoma in situ Adenocarcinoma—endocervical –endometrial –extrauterine –not otherwise specified (NOS) Other malignant neoplasms
Educational notes and suggestions	Should be consistent with clinical followup guidelines published by professional organizations with references included

DESCRIPTION & RATIONALE: The Papanicolaou (Pap) smear is primarily used for the early detection of cervical cancer. The interpretation of Pap smears is as heavily dependent on the collection and fixation technique as it is on the completeness and accuracy of the clinical information provided with the specimen. The patient's age, date of last menstrual period, parity, surgical status, postmenopausal status, use of hormone therapy (including use of oral contraceptives), history of radiation or chemotherapy, history of abnormal vaginal bleeding, and history of previous Pap smears are essential for proper interpretation.

A Schiller's test entails applying an iodine solution to the cervix. Normal cells pick up the iodine and stain brown. Abnormal cells do not pick up any color.

Improvements in specimen preparation have added to the increased quality of screening procedures. The Cytyc ThinPrep PapTest (Cytyc Corporation, Boxborough, MA), approved by the U.S. Food and Drug Administration in 1996, is a technique that provides a uniform monolayer of cells free of debris such as blood and mucus. Computerized scanning systems are also being used to reduce the number of smears that require manual review by a cytotechnologist or pathologist.

There are now some alternatives to cone biopsy and cryosurgery for the treatment of cervical dysplasia. Patients with abnormal Pap smear results may have a cervical loop electrosurgical excision procedure (LEEP) performed to remove or destroy abnormal cervical tissue. In the LEEP procedure, a speculum is inserted into the vagina, the cervix is numbed, and a special electrically charged wire loop is used to painlessly remove the suspicious area. Postprocedure cramping and bleeding can occur. Laser ablation is another technique that can be employed for the precise removal of abnormal cervical tissue. ■

INDICATIONS:

- Assist in the diagnosis of cervical dysplasia
- Assist in the diagnosis of endometriosis, condyloma, and vaginal adenosis
- Assist in the diagnosis of genital infections (herpes, *Candida* spp., *Trichomonas vaginalis,* cytomegalovirus, *Chlamydia,* lymphogranuloma venereum, human papillomavirus, and *Actinomyces* spp.)
- Assist in the diagnosis of primary and metastatic neoplasms
- Evaluate hormonal function

RESULT

Positive findings in: (See table [Bethesda system], presented earlier under "Reference Value")

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- The smear should not be allowed to air dry before fixation.
- Lubricating jelly should not be used on the speculum.
- Improper collection site may result in specimen rejection. Samples for cancer screening are obtained from the posterior vaginal fornix and from the cervix. Samples for hormonal evaluation are obtained from the vagina.
- Douching, sexual intercourse, using tampons, or using vaginal medication within 24 hours prior to specimen collection can interfere with the specimen's results.

- Collection of other specimens prior to the collection of the Pap smear may be cause for specimen rejection.
- Contamination with blood from samples collected during the patient's menstrual period may be cause for specimen rejection.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to establish a histologic diagnosis of cervical and vaginal disease and identify the presence of genital infections.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune and reproductive systems and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related tests, refer to the Immune and Reproductive System tables.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Instruct the patient to avoid douching or sexual intercourse for 24 hours before specimen collection. Verify that the patient is not menstruating. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the procedure. Inform the patient that specimen collection is performed by a health care practitioner specializing in this procedure and takes approximately 5 to 10 minutes.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- If the patient is taking vaginal antibiotic medication, testing should be delayed for 1 month after the treatment has been completed.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Have the patient void before the procedure.
- Have the patient remove clothes below the waist.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
- Assist the patient into a lithotomy position on a gynecologic examination table (with feet in stirrups). Drape the patient's legs.
- A plastic or metal speculum is inserted into the vagina and is opened to gently spread apart the vagina for inspection of the cervix. The speculum may be dipped in warm water to aid in comfortable insertion.
- After the speculum is properly positioned, the cervical and vaginal specimens are obtained. A synthetic fiber

brush is inserted deep enough into the cervix to reach the endocervical canal. The brush is then rotated one turn and removed. The plastic or wooden spatula is used to lightly scrape the cervix and vaginal wall.

Conventional collection:

- Both specimens that are on the brush and spatula are then plated on the glass slide. The brush specimen is plated using a gentle rolling motion, whereas the spatula specimen is plated using a light gliding motion across the slide. The specimens are immediately fixed to the slide with a liquid or spray containing 95% ethanol. The speculum is removed from the vagina. A pelvic and/or rectal exam is usually performed after specimen collection is completed.

ThinPrep collection:

- The ThinPrep bottle lid is opened and removed, exposing the solution. The brush and spatula specimens are then gently swished in the ThinPrep solution to remove the adhering cells. The brush and spatula are then removed from the ThinPrep solution, and the bottle lid is replaced and secured.

General:

- Place samples in properly labeled specimen container and promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Cleanse or allow the patient to cleanse secretions or excess lubricant (if a pelvic and/or rectal examination is also performed) from the perineal area. Provide a sanitary pad if cervical bleeding occurs.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Inform the patient, as appropriate, that repeat testing may be requested in the event of specimen rejection or abnormal findings. Inform the patient that non–sexually active women should begin yearly Pap smears at 18 years of age, and younger sexually active women should begin yearly Pap smears earlier. Pap smears should be repeated more frequently if the results return abnormal. After a hysterectomy, a vaginal cuff Pap smear is used to monitor the cells lining the terminal end of the vagina. Several guidelines differ in their recommendations on when to cease Pap smear testing. Encourage patients to discuss their Pap smear result history and women's health history with their health care provider to determine at what age testing may be terminated. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include bacterial throat culture for gonorrhea, cervical biopsy, and *Chlamydia* group antibody.

PARATHYROID HORMONE: INTACT, C-TERMINAL, AND N-TERMINAL

SYNONYM/ACRONYM: Parathormone, PTH.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Specimen should be transported tightly capped and in an ice slurry.

REFERENCE VALUE: (Method: Immunoassay)

	Conventional Units	SI Units (Conventional Units × 1)
C-terminal		
1–16 y	51–217 pg/mL	51–217 ng/L
Adults	50–330 pg/mL	50–330 ng/L
N-terminal		
2–13 y	14–21 pg/mL	14–21 ng/L
Adult	8–24 pg/mL	8–24 ng/L
Intact		
Cord blood	Less than 3 pg/mL	Less than 3 ng/L
2–20 y	9–52 pg/mL	9–52 ng/L
Adult	10–65 pg/mL	10–65 ng/L

DESCRIPTION & RATIONALE: Parathyroid hormone (PTH) is secreted by the parathyroid glands in response to decreased levels of circulating calcium. PTH assists in the mobilization of calcium from bone into the bloodstream, promoting renal tubular reabsorption of calcium and depression of phosphate reabsorption, thereby reducing calcium excretion and increasing phosphate excretion by the kidneys. PTH also decreases the renal secretion of hydrogen ions, which leads to increased renal excretion of bicarbonate and chloride. PTH enhances renal production of active vitamin D metabolites, causing increased calcium absorption in the small intestine. The net result of PTH action is maintenance of adequate serum calcium levels. In normal individuals, intact PTH has a circulating half-life of about 5 minutes. N-terminal PTH has a circulating half-life of about 2 minutes and is found in very small quantities. Intact and N-terminal PTH are the only biologically active forms of the hormone. Ninety percent of circulating PTH is composed of inactive C-terminal and midregion fragments. PTH is cleared from the body by the kidneys. ■

INDICATIONS:

- Assist in the diagnosis of hyperparathyroidism
- Assist in the diagnosis of suspected secondary hyperparathyroidism due to chronic renal failure, malignant tumors that produce ectopic PTH, and malabsorption syndromes
- Detect incidental damage or inadvertent removal of the parathyroid glands during thyroid or neck surgery
- Differentiate parathyroid and nonparathyroid causes of hypercalcemia
- Evaluate autoimmune destruction of the parathyroid glands
- Evaluate parathyroid response to altered serum calcium levels, especially those that result from malignant processes, leading to decreased PTH production
- Evaluate source of altered calcium metabolism

RESULT

Increased in:

- Fluorosis
- Primary, secondary, or tertiary hyperparathyroidism
- Pseudogout
- Pseudohypoparathyroidism
- Spinal cord trauma
- Zollinger-Ellison syndrome

Decreased in:

- Autoimmune destruction of the parathyroids
- DiGeorge syndrome
- Hyperthyroidism
- Hypomagnesemia
- Nonparathyroid hypercalcemia (in the absence of renal failure)
- Sarcoidosis
- Secondary hypoparathyroidism due to surgery

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase PTH levels include clodronate, dopamine, estrogen/progestin therapy, foscarnet, furosemide, hydrocortisone, isoniazid, lithium, octreotide, pamidronate, phosphates, prednisone, tamoxifen, and verapamil.
- Drugs and vitamins that may decrease PTH levels include alfacalcidol, aluminum hydroxide, calcitriol, cimetidine (C-terminal only), diltiazem, magnesium sulfate, pindolol, prednisone (intact), and vitamin D.
- PTH levels are subject to diurnal variation, with highest levels occurring in the morning.
- PTH levels should always be measured in conjunction with calcium for proper interpretation.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the diagnosis of parathyroid disease and disorders of calcium balance. It is also used to monitor patients undergoing renal dialysis.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine System table.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutra-

ceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.

- Review the procedure with the patient. Early-morning specimen collection is recommended because of the diurnal variation in PTH levels. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- The patient should fast for 12 hours before specimen collection.
- There are no fluid or medication restrictions, unless by medical direction.
- Prepare an ice slurry in a cup or plastic bag to have on hand for immediate transport of the specimen to the laboratory.

Intratest:

- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 12 hours prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis. The sample should be placed in an ice slurry immediately after collection. Information on the specimen label can be protected from water in the ice slurry if the specimen is first placed in a protective plastic bag.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient to resume usual diet, as directed by the health care practitioner.
- *Nutritional considerations:* Patients with abnormal parathyroid levels are also likely to experience the effects of calcium level imbalances. Instruct the patient to report signs and symptoms of hypocalcemia and hypercalcemia to the health care practitioner. (For critical values, signs and symptoms of calcium imbalance, and nutritional information, see monographs titled "Calcium.")
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include calcium (blood and ionized), blood and urine phosphorus, and vitamin D.

PARATHYROID SCAN

SYNONYM/ACRONYM: Parathyroid scintiscan.

AREA OF APPLICATION: Parathyroid.

CONTRAST: Intravenous technetium-99m (Tc-99m) pertechnetate, Tc-99m sestamibi, oral iodine-123, and thallium.

DESCRIPTION & RATIONALE: Parathyroid scanning is performed to assist in the preoperative localization of parathyroid adenomas in clinically proven primary hyperparathyroidism; it is useful for distinguishing between intrinsic and extrinsic parathyroid adenomas. It is also performed after surgery to verify the presence of the parathyroid gland in children, and it is done after thyroidectomy as well.

The radionuclide is administered 10 to 20 minutes before the imaging is performed. The thyroid and surrounding tissues should be carefully palpated.

Fine-needle aspiration biopsy guided by ultrasound is occasionally necessary to differentiate thyroid pathology, as well as pathology of other tissues, from parathyroid neoplasia. ■

INDICATIONS:

- Aid in the diagnosis of hyperparathyroidism
- Differentiate between extrinsic and intrinsic parathyroid adenoma, but not between benign and malignant conditions
- Evaluate the parathyroid in patients with severe hypercalcemia or in patients before parathyroidectomy

RESULT

Normal Findings:

- No areas of increased perfusion or uptake in the thyroid or parathyroid

Abnormal Findings:

- Intrinsic and extrinsic parathyroid adenomas

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Ingestion of foods containing iodine (e.g., iodized salt) and medications containing iodine (e.g., cough syrup, potassium iodide, vitamins, Lugol's solution, thyroid replacement medications), which can decrease uptake of the radionuclide

- Recent use of iodinated contrast medium for radiographic studies or recently performed nuclear medicine procedures, which can affect the uptake of the radionuclide
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images

Other considerations:

- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the parathyroid glands.
- Obtain a history of the patient's complaints and symptoms, including a list of known allergens.
- Obtain a history of the patient's immune system, as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Immune System table.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Determine whether the patient has had any recent intake of iodine.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Explain the purpose of the test and how the procedure is performed. Inform the patient that the procedure is performed in a nuclear medicine department, usually by a technologist and support staff, and takes approximately 30 to 60 minutes. Inform the patient that the technologist will administer an intravenous injection of the radionuclide and that he or she will need to return 2 to 3 hours later for the scan.
- Record the date of the last menstrual period. Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast mediums or barium.
- Ensure that the patient has not been scheduled for more than one radionuclide scan on the same day. Multiple procedures on the same day may interfere with interpretation of results.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.

Intratest:

- Make sure jewelry, chains, and any other metallic objects have been removed from the neck area.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Wear gloves during the radionuclide injection and while handling the patient's urine.
- Administer technetium-99m (Tc-99m) pertechnetate intravenously before scanning.
- To scan the parathyroid gland, the patient is placed in a supine position under a radionuclide gamma camera 15 minutes after the radionuclide injection. Imaging is performed over the anterior neck area.
- With the patient in the same position, Tc-99m sestamibi is injected, and after 10 minutes a second image is obtained and stored in the computer. The computer subtracts the technetium-visualized thyroid structures from the thallium accumulation in a parathyroid adenoma.
- Iodine-123 may be administered orally in place of Tc-99m pertechnetate; the imaging sequence, as described previously, is performed 24 hours later.
- The images are recorded on film or stored electronically for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Assess injection site for bleeding, hematoma formation, and inflammation. Apply warm soaks to promote comfort if a hematoma develops.
- Advise patient to drink increased amounts of fluids for 24 to 48 hours to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hours.
- Instruct the patient to flush the toilet immediately after each voiding following the procedure, and to wash hands meticulously with soap and water after each voiding for 24 hours after the procedure.
- Tell all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the thorax and magnetic resonance imaging of the chest.

PARTIAL THROMBOPLASTIN TIME, ACTIVATED

SYNONYM/ACRONYM: APTT.

SPECIMEN: Plasma (1 mL) collected in a completely filled blue-top (sodium citrate) tube.

REFERENCE VALUE: (Method: Clot detection) 25 to 39 seconds. Reference ranges vary with respect to the equipment and reagents used to perform the assay.

DESCRIPTION & RATIONALE: The activated partial thromboplastin time (APTT) coagulation test evaluates the function of the intrinsic (factors XII, XI, IX, and VIII) and common (factors V, X, II, and I) pathways of the coagulation sequence, specifically the intrinsic thromboplastin system. It represents the time required for a firm fibrin clot to form after tissue thromboplastin or phospholipid reagents similar to thromboplastin and calcium are added to the specimen. The APTT is abnormal in 90% of patients with coagulation disorders and is useful in monitoring the inactivation of factor II effect of heparin therapy. The test is prolonged when there is a 30% to 40% deficiency in one of the factors required, or when factor inhibitors (e.g., antithrombin III, protein C, or protein S) are present. The APTT has additional activators, such as kaolin, Celite, or elegiac acid, that more rapidly activate factor XII, making this test faster and more reliably reproducible than the partial thromboplastin time (PTT). A comparison between the results of APTT and prothrombin time (PT) tests can allow some inferences to be made that a factor deficiency exists. A normal APTT with a prolonged PT can only occur with factor VII deficiency. A prolonged APTT with a normal PT could indicate a deficiency in factors XII, XI, IX, VIII, and VIII:C (von Willebrand factor). Factor deficiencies can also be identified by correction or substitution studies using normal serum. These studies are easy to perform and are accomplished by adding plasma from a normal patient to a sample from a patient suspected to be factor deficient. When the APTT is repeated and is corrected, or within the reference range, it can be assumed that the prolonged APTT is caused by a factor deficiency. The administration of prophylactic low-dose heparin does not require serial monitoring of APTT. (For more information on factor deficiencies, see monograph titled "Fibrinogen.") ■

INDICATIONS:

- Detect congenital deficiencies in clotting factors, as seen in diseases such as hemophilia A (factor VIII) and hemophilia B (factor IX)
- Evaluate response to anticoagulant therapy with heparin or coumarin derivatives
- Identify individuals who may be prone to bleeding during surgical, obstetric, dental, or invasive diagnostic procedures
- Identify the possible cause of abnormal bleeding, such as epistaxis, hematoma, gingival bleeding, hematuria, and menorrhagia
- Monitor the hemostatic effects of conditions such as liver disease, protein deficiency, and fat malabsorption

RESULT

Prolonged in:

- Afibrinogenemia
- Circulating products of fibrin and fibrinogen degradation
- Disseminated intravascular coagulation
- Factor deficiencies
- Hemodialysis patients
- Polycythemia
- Severe liver disease
- Vitamin K deficiency
- Von Willebrand's disease

CRITICAL VALUES: N/A

Greater than 70 seconds.

The requesting health care practitioner should also be notified if the APTT is less than 53 seconds in a patient receiving heparin therapy. Low values indicate that the therapy is providing inadequate anticoagulation.

Note and immediately report to the health care practitioner any critically increased or decreased values and related symptoms. Important signs to note are prolonged bleeding, hematoma at the puncture site, hemorrhage, blood in the stool, bleeding gums, and shock. Monitoring vital signs and neurologic changes until values are within normal range is indicated. Administration of protamine sulfate may be requested.

INTERFERING FACTORS:

- Drugs and vitamins such as anistreplase, antihistamines, chlorpromazine, salicylates, and ascorbic acid may cause prolonged APTT.
- Anticoagulant therapy with heparin will prolong the APTT.
- Copper is a component of factor V, and severe copper deficiencies may result in prolonged APTT values.
- Traumatic venipunctures can activate the coagulation sequence by contamination of the sample with tissue thromboplastin and can produce falsely shortened results.
- Failure to fill the tube sufficiently to yield a proper blood-to-anticoagulant ratio invalidates the results and is reason for specimen rejection.
- Excessive agitation that causes sample hemolysis can falsely shorten the APTT because the hemolyzed cells activate plasma-clotting factors.
- Inadequate mixing of the tube can produce erroneous results.
- Specimens left unprocessed for longer than 4 hours should be rejected for analysis.
- High platelet count or inadequate centrifugation will result in decreased values.
- Hematocrit greater than 55% may cause falsely prolonged results because of anticoagulant excess. The excess anticoagulant chelates the calcium reagent in the test system, making it unavailable to react properly with the patient sample.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate coagulation disorders and monitor therapy.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic and hepatobiliary systems, history of any bleeding disorders, and results of previously performed laboratory tests (especially bleeding time, complete blood count, PTT, platelets, and PT), surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic and Hepatobiliary System tables.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, acetylsalicylic acid, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation. It is recommended that use of these products be discontinued 14 days before dental or surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results. If the patient is receiving anticoagulant therapy, note the time and amount of the last dose.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL blue-top tube. Fill the tube completely. *Important note:* Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It is important to inquire from the laboratory which concentration it recommends, because each concentration will have its own specific reference range.
- When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and red-top tubes. When coagulation testing is the only work to be done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with tissue thromboplastin.
- Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed specimens stored in unopened tubes is that testing should be completed within 1 to 4 hours of collection.

- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient to report severe bruising or bleeding from any areas of the skin or mucous membranes.
- Inform the patient with prolonged APTT values of the importance of taking precautions against bruising and bleeding, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of acetylsalicylic acid and similar products, and avoidance of intramuscular injections.
- Inform the patient of the importance of periodic laboratory testing while taking an anticoagulant.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include antithrombin III, bleeding time, coagulation factors, complete blood count, copper, fibrin degredation products, platelet count, protein C, protein S, prothrombin time and International Normalized Ratio, and vitamin K.

PARVOVIRUS B19 IMMUNOGLOBULIN G AND IMMUNOGLOBULIN M ANTIBODIES

SYNONYM/ACRONYM: N/A.

SPECIMEN: Serum (2 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Immunoassay)

Negative	Less than 0.8
Equivocal	0.8–1.2

DESCRIPTION & RATIONALE: Parvovirus B19, a single-stranded DNA virus transmitted by respiratory secretions, is the only parvovirus known to infect humans. Its primary site of replication is in red blood cell precursors in the bone marrow. It is capable of causing disease along a wide spectrum ranging from a self-limited erythema (fifth disease) to bone marrow failure or aplastic crisis in patients with sickle cell anemia, spherocytosis, or thalassemia. Fetal hydrops and spontaneous abortion may also occur as a result of infection during pregnancy. The incubation period is approximately 1 week after exposure. B19-specific antibodies appear in the serum approximately 3 days after the onset of symptoms. The presence of immunoglobulin M (IgM) antibodies indicates acute infection. The presence of IgG antibodies indicates past infection and is believed to confer lifelong immunity. Parvovirus can also be detected by DNA hybridization using a polymerase chain reaction. ■

INDICATIONS: Assist in establishing a diagnosis of parvovirus B19 infection

RESULT

Positive findings in:

- Arthritis
- Erythema infectiosum (fifth disease)
- Erythrocyte aplasia
- Hydrops fetalis

Negative findings in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS: Immunocompromised patients may not develop sufficient antibody to be detected.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in confirming past or present parvovirus infection.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune System table.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Inform the patient that a subsequent sample will be required in 7 to 14 days. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should

be taken to avoid the use of equipment containing latex.

- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to lack of neuromuscular control, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the Myasthenia Gravis Foundation of America *(http://www.myasthenia.org)* and Muscular Dystrophy Association *(http://www.mdausa.org)*.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Emphasize the need for the patient to return to have a convalescent blood sample taken in 7 to 14 days. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include bone marrow biopsy, complete blood count, hemoglobin electrophoresis, red blood cell morphology, and sickle cell screen.

PERICARDIAL FLUID ANALYSIS

SYNONYM/ACRONYM: None.

SPECIMEN: Pericardial fluid (5 mL) collected in a red- or green-top (heparin) tube for glucose, a lavender-top (EDTA) tube for cell count, and sterile containers for microbiology specimens; 200 to 500 mL of fluid in a clear container for cytology. Ensure that there is an equal amount of fluid relative to fixative in the container for cytology.

REFERENCE VALUE: (Method: Spectrophotometry for glucose; automated or manual cell count, macroscopic examination of cultured organisms, and microscopic examination of specimen for microbiology and cytology; microscopic examination of cultured microorganisms)

Pericardial Fluid	Reference Value
Appearance	Clear
Color	Pale yellow
Glucose	Parallel serum values
Red blood cell count	None seen
White blood cell count	Less than 1000/mm^3
Culture	No growth
Gram stain	No organisms seen
Cytology	No abnormal cells seen

DESCRIPTION & RATIONALE: The heart is located within a protective membrane called the *pericardium.* The fluid between the pericardial membranes is called *serous fluid.* Normally only a small amount of fluid is present because the rates of fluid production and absorption are about the same. Many abnormal conditions can result in the buildup of fluid within the pericardium. Specific tests are usually ordered in addition to a common battery of tests used to distinguish a transudate from an exudate. *Transudates* are effusions that form as a result of a systemic disorder that disrupts the regulation of fluid balance, such as a suspected perforation. *Exudates* are caused by conditions involving the tissue of the membrane itself, such as an infection or malignancy. Fluid is withdrawn from the pericardium by needle aspiration and tested as listed in the previous and following tables. ■

Characteristic	Transudate	Exudate
Appearance	Clear	Cloudy or turbid
Specific gravity	Less than 1.015	Greater than 1.015
Total protein	Less than 2.5 g/dL	Greater than 3.0 g/dL
Fluid-to–serum protein ratio	Less than 0.5	Greater than 0.5
LDH	Parallels serum value	Less than 200 U/L
Fluid-to–serum LDH ratio	Less than 0.6	Greater than 0.6
Fluid cholesterol	Less than 55 mg/dL	Greater than 55 mg/dL
White blood cell count	Less than 100/mm^3	Greater than 1000/mm^3

LDH = lactate dehydrogenase.

INDICATIONS:

- Evaluate effusion of unknown etiology
- Investigate suspected hemorrhage, immune disease, malignancy, or infection

RESULT

Increased in (condition/test showing increased result):

- Bacterial pericarditis (red blood cell [RBC] count, white blood cell [WBC] count with a predominance of neutrophils)
- Hemorrhagic pericarditis (RBC count, WBC count)
- Malignancy (RBC count, abnormal cytology)
- Post–myocardial infarction syndrome, also called Dressler's syndrome (RBC count, WBC count with a predominance of neutrophils)
- Rheumatoid disease or systemic lupus erythematosus (RBC count, WBC count)
- Tuberculous or fungal pericarditis (RBC count, WBC count with a predominance of lymphocytes)
- Viral pericarditis (RBC count, WBC count with a predominance of neutrophils)

Decreased in (condition/test showing decreased result):

- Bacterial pericarditis (glucose)
- Malignancy (glucose)
- Rheumatoid disease or systemic lupus erythematosus (glucose)

CRITICAL VALUES:

Note and immediately report to the health care practitioner positive culture results, if ordered, and related symptoms.

INTERFERING FACTORS:

- Bloody fluid may be the result of a traumatic tap.
- Unknown hyperglycemia or hypoglycemia may be misleading in the comparison of fluid and serum glucose levels. Therefore, it is advisable to collect comparative serum samples a few hours before performing pericardiocentesis.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to classify the type of

effusion being produced and identify the cause of its accumulation.

- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular and immune systems, any bleeding disorders, and results of previously performed laboratory tests (especially bleeding time, complete blood count, partial thromboplastin time, platelets, and prothrombin time), surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Cardiovascular and Immune System tables.
- Note any recent procedures that can interfere with test results.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, acetylsalicylic acid, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that it may be necessary to shave the site before the procedure. Address concerns about pain related to the procedure. Explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to needle insertion through the chest wall. Explain to the patient that any discomfort with the needle insertion will be minimized with local anesthetics and systemic analgesics. Explain that the anesthetic injection may cause a stinging sensation. Explain that, after the skin has been anesthetized, a large needle will be inserted through the chest to obtain the fluid. Inform the patient that specimen collection is performed under sterile conditions by a health care practitioner specializing in this procedure. The procedure usually takes approximately 30 minutes to complete.
- Explain that an intravenous (IV) line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Food and fluids should be restricted for 6 to 8 hours before the procedure, as directed by the health care practitioner, unless the procedure is performed in an emergency situation to correct pericarditis. The requesting health care practitioner may request that anticoagulants and aspirin be withheld. The amount of days to withhold medication is dependent on the type of anticoagulant.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that the patient has complied with dietary and fluids restrictions; assure that food has been restricted for at least 6 to 8 hours prior to the procedure.
- Ensure that anticoagulant therapy has been withheld for the appropriate amount of days prior to the procedure. Notify health care practitioner if patient anticoagulant therapy has not been withheld.
- Have emergency equipment readily available.
- Have the patient void before the procedure.
- Have the patient remove clothes above the waist and put on a gown.

- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
- Establish an IV line to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.
- Assist the patient into a comfortable supine position with the head elevated 45° to 60°.
- Prior to the administration of local anesthesia, cleanse the site with an antiseptic solution, and drape the area with sterile towels. The skin at the injection site is then anesthetized.
- The precordial (V) cardiac lead wire is attached to the cardiac needle with an alligator clip. The cardiac needle is inserted just below and to the left of the breastbone, and fluid is removed.
- Monitor vital signs every 15 minutes for signs of hypovolemia or shock. Monitor electrocardiogram for needle-tip positioning to indicate accidental puncture of the right atrium.
- The needle is withdrawn, and slight pressure is applied to the site. Apply a sterile dressing to the site.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- Place samples in properly labeled specimen container, and promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet and medications, as directed by the health care practitioner.
- Monitor vital signs and cardiac status every 15 minutes for the first hour, every 30 minutes for the next 2 hours, every hour for the next 4 hours, and every 4 hours for the next 24 hours. Take the patient's temperature every 4 hours for 24 hours. Monitor intake and output for 24 hours. Notify the health care practitioner if temperature is elevated. Protocols may vary from facility to facility.
- Observe the patient for signs of respiratory and cardiac distress, such as shortness of breath, cyanosis, or rapid pulse.
- Continue IV fluids until vital signs are stable and the patient can resume fluid intake independently.
- Inform the patient that 1 hour or more of bed rest is required after the procedure.
- Assess the puncture site for bleeding or drainage and signs of inflammation each time vital signs are taken and daily thereafter for several days. Report to health care practitioner if bleeding is present.
- Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the health care practitioner.
- Administer antibiotics, as ordered, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.

- Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, if appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include aspartate aminotransferase, atrial natriuretic peptide, bacterial culture, blood gases, B-type natriuretic peptide, CA 15–3, CA 19–9, CA 125, carcinoembryonic antigen, creatine kinase and isoenzymes, α_1-fetoprotein, fungal culture, homocysteine, lactate dehydrogenase and isoenzymes, magnesium, mycobacterial culture, myoglobin, troponin, and viral culture.

PERITONEAL FLUID ANALYSIS

SYNONYM/ACRONYM: Ascites fluid analysis.w

SPECIMEN: Peritoneal fluid (5 mL) collected in a red- or green-top (heparin) tube for amylase, glucose, and alkaline phosphatase; lavender-top (EDTA) tube for cell count; sterile containers for microbiology specimens; 200 to 500 mL of fluid in a clear container with anticoagulant for cytology. Ensure that there is an equal amount of fluid relative to fixative in the container for cytology.

REFERENCE VALUE: (Method: Spectrophotometry for glucose, amylase, and alkaline phosphatase; automated or manual cell count, macroscopic examination of cultured organisms, and microscopic examination of specimen for microbiology and cytology; microscopic examination of cultured microorganisms)

Peritoneal Fluid	Reference Value
Appearance	Clear
Color	Pale yellow
Amylase	Parallel serum values

Peritoneal Fluid	Reference Value
Alkaline phosphatase	Parallel serum values
Glucose	Parallel serum values
Red blood cell count	Less than 100,000/mm^3
White blood cell count	Less than 300/mm^3
Culture	No growth
Acid-fast stain	No organisms seen
Gram stain	No organisms seen
Cytology	No abnormal cells seen

DESCRIPTION & RATIONALE: The peritoneal cavity and organs within it are lined with a protective membrane. The fluid between the membranes is called *serous fluid.* Normally only a small amount of fluid is present because the rates of fluid production and absorption are about the same. Many abnormal conditions can result in the buildup of fluid within the peritoneal cavity. Specific tests are usually ordered in addition to a common battery of tests used to distinguish a transudate from an exudate.

Transudates are effusions that form as a result of a systemic disorder that disrupts the regulation of fluid balance, such as a suspected perforation. *Exudates* are caused by conditions involving the tissue of the membrane itself, such as an infection or malignancy. Fluid is withdrawn from the peritoneal cavity by needle aspiration and tested as listed in the previous and following tables. ■

INDICATIONS:

- Evaluate ascites of unknown cause

Characteristic	Transudate	Exudate
Appearance	Clear	Cloudy or turbid
Specific gravity	Less than 1.015	Greater than 1.015
Total protein	Less than 2.5 g/dL	Greater than 3.0 g/dL
Fluid-to–serum protein ratio	Less than 0.5	Greater than 0.5
LDH	Parallels serum value	Less than 200 U/L
Fluid-to–serum LDH ratio	Less than 0.6	Greater than 0.6
Fluid cholesterol	Less than 55 mg/dL	Greater than 55 mg/dL
White blood cell count	Less than 100/mm^3	Greater than 1000/mm^3

LDH = lactate dehydrogenase.

- Investigate suspected peritoneal rupture, perforation, malignancy, or infection

RESULT

Increased in (condition/test showing increased result):

- Abdominal malignancy (red blood cell [RBC] count, carcinoembryonic antigen, abnormal cytology)
- Abdominal trauma (RBC count greater than 100,000/mm^3)
- Ascites caused by cirrhosis (white blood cell [WBC] count, neutrophils greater

than 25% but less than 50%, absolute granulocyte count greater than 250/mm^3)

- Bacterial peritonitis (WBC count, neutrophils greater than 50%, absolute granulocyte count greater than 250/mm^3)
- Peritoneal effusion due to gastric strangulation, perforation, or necrosis (amylase, ammonia, alkaline phosphatase)
- Peritoneal effusion due to pancreatitis, pancreatic trauma, or pancreatic pseudocyst (amylase)
- Rupture or perforation of urinary bladder (ammonia, creatinine, urea)
- Tuberculous effusion (elevated lymphocyte count, positive acid-fast bacillus smear and culture [25% to 50% of cases])

Decreased in (condition/test showing decreased result):

- Abdominal malignancy (glucose)
- Tuberculous effusion (glucose)

CRITICAL VALUES:

Note and immediately report to the health care practitioner positive culture results, if ordered, and related symptoms.

INTERFERING FACTORS:

- Bloody fluids may result from a traumatic tap.
- Unknown hyperglycemia or hypoglycemia may be misleading in the comparison of fluid and serum glucose levels. Therefore, it is advisable to collect comparative serum samples a few hours before performing paracentesis.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to classify the type of effusion being produced and identify the cause of its accumulation.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal and immune systems, any bleeding disorders, and results of previously performed laboratory tests (especially bleeding time, complete blood count, partial thromboplastin time, platelets, and prothrombin time), surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Gastrointestinal and Immune System tables.
- Note any recent procedures that can interfere with test results.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, acetylsalicylic acid, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. If patient has ascites, obtain weight and measure abdominal girth. Inform the patient that it may be necessary to shave the site before the procedure. Address concerns about pain related to the procedure. Explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to needle insertion through the abdomen wall. Explain to the patient that any discomfort with the needle insertion will be minimized with local anesthetics and systemic analgesics. Explain that the anesthetic injection may cause an

initial stinging sensation. Explain that, after the skin has been anesthetized, a large needle will be inserted through the abdominal wall and a "popping" sensation may be experienced as the needle penetrates the peritoneum. Inform the patient that specimen collection is performed under sterile conditions by a health care practitioner specializing in this procedure. The procedure usually takes approximately 30 minutes to complete.

- Explain that an intravenous (IV) line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food or fluid restrictions, unless by medical direction. The requesting health care practitioner may request that anticoagulants and aspirin be withheld. The amount of days to withhold medication is dependent on the type of anticoagulant.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that anticoagulant therapy has been withheld for the appropriate amount of days prior to the procedure. Notify the health care practitioner if patient anticoagulant therapy has not been withheld.
- Have emergency equipment readily available.
- Have the patient void or catheterize the patient to avoid accidental puncture of the bladder if he or she is unable to void.
- Have the patient remove clothing and change into a gown for the procedure.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
- Record baseline vital signs and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
- Establish an IV line to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.
- Assist the patient to a comfortable seated position with feet and back supported or in high Fowler's position.
- Prior to the administration of local anesthesia, shave and cleanse the site with an antiseptic solution, and drape the area with sterile towels. The skin at the injection site is then anesthetized.
- The paracentesis needle is inserted 1 to 2 inches below the umbilicus, and fluid is removed. If lavage fluid is required (helpful if malignancy is suspected), saline or Ringer's lactate can be infused via the needle over a 15- to 20-minute period before the lavage fluid is removed. Monitor vital signs every 15 minutes for signs of hypovolemia or shock.
- No more than 1500 to 2000 mL of fluid should be removed at a time, even in the case of a therapeutic paracentesis, because of the risk of hypovolemia and shock.
- The needle is withdrawn, and slight pressure applied to the site. Apply a sterile dressing to the site.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- Place samples in properly labeled specimen container, and promptly transport the specimen to the laboratory for processing and analysis.

- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual medications, as directed by the health care practitioner.
- Monitor vital signs every 15 minutes for the first hour, every 30 minutes for the next 2 hours, every hour for the next 4 hours, and every 4 hours for the next 24 hours. Take the patient's temperature every 4 hours for 24 hours. Monitor intake and output for 24 hours. Notify the health care practitioner if temperature is elevated. Protocols may vary from facility to facility.
- Assess the puncture site for bleeding or drainage and signs of inflammation each time vital signs are taken and daily thereafter for several days. Report to health care practitioner if bleeding is present.
- If a large amount of fluid was removed, obtain weight and measure abdominal girth.
- Inform the patient that 1 hour or more of bed rest is required after the procedure.
- Instruct the patient to immediately report severe abdominal pain (*note:* rigidity of abdominal muscles indicates developing peritonitis). Report to health care practitioner if abdominal rigidity or pain is present.
- Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the health care practitioner.
- Administer antibiotics, as ordered, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, if appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include bacterial culture, CA 15-3, CA 19-9, CA 125, carcinoembryonic antigen, fungal culture, mycobacterial culture, and viral culture.

PHOSPHORUS, BLOOD

SYNONYMS/ACRONYM: Inorganic phosphorus, phosphate, PO_4.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 0.323)
0–5 d	4.6–8.0 mg/dL	1.5–2.6 mmol/L
1–3 y	3.9–6.5 mg/dL	1.3–2.1 mmol/L
4–6 y	4.0–5.4 mg/dL	1.3–1.7 mmol/L
7–11 y	3.7–5.6 mg/dL	1.2–1.8 mmol/L
12–13 y	3.3–5.4 mg/dL	1.1–1.7 mmol/L
14–15 y	2.9–5.4 mg/dL	0.9–1.7 mmol/L
16–19 y	2.8–4.6 mg/dL	0.9–1.5 mmol/L
Adult	2.5–4.5 mg/dL	0.8–1.4 mmol/L

DESCRIPTION & RATIONALE: Phosphorus, in the form of phosphate, is distributed throughout the body. Approximately 85% of the body's phosphorus is stored in bones; the remainder is found in cells and body fluids. It is the major intracellular anion and plays a crucial role in cellular metabolism, maintenance of cellular membranes, and formation of bones and teeth. Phosphorus also indirectly affects the release of oxygen from hemoglobin by affecting the formation of 2,3-bisphosphoglycerate. Levels of phosphorus are dependent on dietary intake.

Phosphorus excretion is regulated by the kidneys. Calcium and phosphorus are interrelated with respect to absorption and metabolic function. They have an inverse relationship with respect to concentration: serum phosphorus is increased when serum calcium is decreased. Hyperphosphatemia can result in an infant fed only cow's milk during the first few weeks of life because of the combination of a high phosphorus content in cow's milk and the inability of infants' kidneys to clear the excess phosphorus. ■

INDICATIONS:

- Assist in establishing a diagnosis of hyperparathyroidism
- Assist in the evaluation of renal failure

Result

Increased in:

- Acromegaly
- Bone metastases
- Diabetic ketoacidosis
- Excessive levels of vitamin D
- Hyperthermia
- Hypocalcemia
- Hypoparathyroidism
- Lactic acidosis
- Milk alkali syndrome
- Pseudohypoparathyroidism
- Pulmonary embolism
- Renal failure
- Respiratory acidosis

Decreased in:

- Acute gout
- Alcohol withdrawal
- Gram-negative bacterial septicemia
- Growth hormone deficiency
- Hyperalimentation therapy
- Hypercalcemia
- Hyperinsulinism
- Hyperparathyroidism
- Hypokalemia
- Impaired renal absorption
- Malabsorption syndromes
- Malnutrition
- Osteomalacia
- Parathyroid hormone–producing tumors
- Primary hyperparathyroidism
- Renal tubular acidosis
- Renal tubular defects
- Respiratory alkalosis
- Respiratory infections
- Rickets
- Salicylate poisoning
- Severe burns
- Severe vomiting and diarrhea
- Vitamin D deficiency

Critical Values:

Values less than 1.0 mg/dL may have significant effects on the neuromuscular, gastrointestinal, cardiopulmonary, and skeletal systems.

Note and immediately report to the health care practitioner any critically increased or decreased values and related symptoms. Interventions including intravenous (IV) replacement therapy with sodium or potassium phosphate may be necessary. Close monitoring of both phosphorus and calcium is important during replacement therapy.

Interfering Factors:

- Drugs that may increase phosphorus levels include anabolic steroids, β-adrenergic blockers, ergocalciferol, furosemide, hydrochlorothiazide, methicillin (occurs with nephrotoxicity), oral contraceptives, parathyroid extract, phosphates, sodium etidronate, tetracycline (occurs with nephrotoxicity), and vitamin D.
- Drugs that may decrease phosphorus levels include acetazolamide, albuterol, aluminum salts, amino acids (via IV hyperalimentation), anesthetic agents, anticonvulsants, calcitonin, epinephrine, fibrin hydrolysate, fructose, glucocorticoids, glucose, insulin, mannitol, oral contraceptives, pamidronate, phenothiazine, phytate, and plicamycin.
- Serum phosphorus levels are subject to diurnal variation: They are highest in late morning and lowest in the evening;

therefore, serial samples should be collected at the same time of day for consistency in interpretation.

- Hemolysis will falsely increase phosphorus values.
- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, thereby falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is present in the IV solution, thereby falsely increasing the result.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the general evaluation of multiple body systems.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine, gastrointestinal, genitourinary, and musculoskeletal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine, Gastrointestinal, Genitourinary, and Musculoskeletal System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Severe hypophosphatemia is common in elderly patients or patients who have been hospitalized for long periods of time. Good dietary sources of phos-

phorus include meat, dairy products, nuts, and legumes.

- *Nutritional considerations:* To decrease phosphorus levels to normal in the patient with hyperphosphatemia, dietary restriction may be recommended. Other interventions may include the administration of phosphate binders or administration of calcitriol (the activated form of vitamin D).
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider.
- Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include calcitonin, calcium, collagen cross-linked N-telopeptides, growth hormone, kidney stone analysis, osteocalcin, parathyroid hormones, urine phosphorus, and vitamin D.

PHOSPHORUS, URINE

SYNONYM/ACRONYM: Urine phosphate.

SPECIMEN: Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

REFERENCE VALUE: (Method: Spectrophotometry) Reference values are dependent on phosphorus and calcium intake. Phosphate excretion exhibits diurnal variation and is significantly higher at night.

Conventional Units	SI Units (Conventional Units × 32.3)
0.4–1.3 g/24 h	12.9–42.0 g/24 h

DESCRIPTION & RATIONALE: Phosphorus, in the form of phosphate, is distributed throughout the body. Approximately 85% of the body's phosphorus is stored in bones; the remainder is found in cells and body fluids. It is the major intracellular anion and plays a crucial role in cellu-

lar metabolism, maintenance of cellular membranes, and formation of bones and teeth. Phosphorus also indirectly affects the release of oxygen from hemoglobin by affecting the formation of 2,3-bisphosphoglycerate. Levels of phosphorus are dependent on dietary intake.

Analyzing urinary phosphorus levels can provide important clues to the functioning of the kidneys and other major organs. Tests for phosphorus in urine usually involve timed urine collections over a 12- or 24-hour period. Measurement of random specimens may also be requested. Children with thalassemia may have normal phosphorus absorption but increased excretion, which may result in a phosphorus deficiency. ■

INDICATIONS:

- Assist in the diagnosis of hyperparathyroidism
- Assist in the evaluation of calcium and phosphorus balance
- Assist in the evaluation of nephrolithiasis
- Assist in the evaluation of renal tubular disease

RESULT

Increased in:

- Abuse of diuretics
- Primary hyperparathyroidism
- Renal tubular acidosis
- Vitamin D deficiency

Decreased in:

- Hypoparathyroidism
- Pseudohypoparathyroidism
- Vitamin D intoxication

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs and vitamins that can cause an increase in urine phosphorus levels include acetazolamide, acetylsalicylic acid, alanine, bismuth salts, calcitonin, corticosteroids, dihydrotachysterol, glycine, hydrochlorothiazide, metolazone, parathyroid extract, parathyroid hormone, phosphates, tryptophan, valine, and vitamin D.
- Drugs that can cause a decrease in urine phosphorus levels include aluminum-containing antacids.
- Urine phosphorus levels are subject to diurnal variation: Output is highest in the afternoon, which is why 24-hour urine collections are recommended.
- All urine voided for the timed collection period must be included in the collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate calcium and phosphorus balance.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine and genitourinary systems, as well as results results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine and Genitourinary System tables.
- Obtain a list of the medications the patient is taking, including herbs,

nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.

- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
- Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to avoid excessive exercise and stress during the 24-hour collection of urine.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with activity restrictions and pretesting preparations; assure that excessive exercise and stress have been restricted during the 24-hour procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection.

Random specimen (collect in early morning):

Clean-catch specimen:

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling catheter:

- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 minutes before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Timed specimen:

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m.,

if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container.

- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container's label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.

General:

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- *Nutritional considerations:* Vitamin D is necessary for the body to absorb phosphorus. Vitamin D is added to food products such as milk, cheese, and orange juice. The recommended daily intake of vitamin D is 200 IU per day.
- Increased urine phosphorus levels may be associated with the formation of kidney stones. Educate the patient, if appropriate, on the importance of drinking a sufficient amount of water when kidney stones are suspected.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include calcitonin, blood and urine calcium, kidney stone analysis, parathyroid hormone, blood phosphorus, and urinalysis.

PLASMINOGEN

SYNONYM/ACRONYM: Profibrinolysin, PMG.

SPECIMEN: Plasma (1 mL) collected in blue-top (sodium citrate) tube.

REFERENCE VALUE: (Method: Chromogenic substrate) 80% to 120% of normal for plasma.

DESCRIPTION & RATIONALE: Plasminogen is a plasma glycoprotein. It is the circulating, inactive precursor to plasmin. Damaged tissues release a substance called *plasminogen activator* that initiates the conversion of plasminogen to plasmin. Plasmin participates in fibrinolysis and is capable of degrading fibrin, factor I (fibrinogen), factor V, and factor VIII. (For more information on fibrin degradation, see monograph titled "Fibrinogen.") ■

INDICATIONS: Evaluate the level of circulating plasminogen in patients with thrombosis or disseminated intravascular coagulation (DIC)

RESULT

Increased in:

- Pregnancy (late)

Decreased in:

- DIC
- Fibrinolytic therapy with tissue plasminogen activators such as streptokinase or urokinase
- Hereditary deficiency
- Liver disease
- Neonatal hyaline membrane disease
- Postsurgical period

CRITICAL VALUES: N/A

INTERFERING FACTORS: Drugs that may decrease plasminogen levels include streptokinase and urokinase.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate thrombotic disorders and monitor thrombolytic therapy.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic System table.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects

can be taken into consideration when reviewing results.

- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions and follow the general guidelines in Appendix A. Positively identify the patient and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL blue-top tube. *Important note:* Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It is important to inquire from the laboratory which concentration it recommends, because each concentration will have its own specific reference range.
- When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and red-top tubes. When coagulation testing is the only work to be done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with tissue thromboplastin, which can falsely decrease values.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed specimens stored in unopened tubes is that testing should be completed within 1 to 4 hours of collection.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include coagulation factors, fibrin degradation products, and fibrinogen.

PLATELET ANTIBODIES

SYNONYMS/ACRONYMS: Antiplatelet antibody; platelet-bound IgG/IgM, direct and indirect.

SPECIMEN: Serum (1 mL) collected in a red-top tube for indirect immunoglobulin G (IgG) antibody. Whole blood (7 mL) collected in lavender-top (EDTA) tube for direct antibody.

REFERENCE VALUE: (Method: Solid-phase hemagglutination and flow cytometry) Negative.

DESCRIPTION & RATIONALE: Platelet antibodies can be formed by autoimmune response, or they can be acquired in reaction to transfusion products. Platelet autoantibodies are immunoglobulins of autoimmune origin (i.e., immunoglobulin G), and they are present in various autoimmune disorders, including thrombocytopenias. Platelet alloantibodies develop in patients who become sensitized to platelet antigens of transfused blood. As a result, destruction of both donor and native platelets occurs along with a shortened survival time of platelets in the transfusion recipient. The platelet antibody detection test is also used for platelet typing, which allows compatible platelets to be transfused to patients with disorders such as aplastic anemia and cancer. Platelet typing decreases the alloimmunization risk resulting from repeated transfusions from random donors. Platelet typing may also provide additional support for a diagnosis of post-transfusional purpura. ■

INDICATIONS:

- Assist in the detection of platelet alloimmune disorders
- Determine platelet type for refractory patients

RESULT

Increased in:

- Acquired immunodeficiency syndrome
- Acute myeloid leukemia
- Idiopathic thrombocytopenic purpura
- Immune complex diseases
- Multiple blood transfusions
- Multiple myeloma
- Neonatal immune thrombocytopenia
- Paroxysmal hemoglobinuria
- Rheumatoid arthritis
- Systemic lupus erythematosus
- Thrombocytopenias provoked by drugs (see monograph titled "Platelet Count")

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS: Hemolyzed or clotted specimens will affect results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate thrombocytopenia.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic and immune systems, a history of any bleeding disorders, and results of previously performed laboratory tests (especially bleeding time, complete blood count, partial thromboplastin time, prothrombin time, and platelets), surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic and Immune System tables.
- Obtain a list of the medications the patient is taking, including include anticoagulant therapy, acetylsalicylic acid, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation. It is recommended that use be discontinued 14 days before dental or surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top and a 7-mL lavender-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Note the patient's response to platelet transfusions.
- Instruct the patient to report severe bruising or bleeding from any areas of the skin or mucous membranes.
- Inform the patient who has developed platelet antibodies of the importance of taking precautions against bruising and bleeding, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of acetylsalicylic acid and similar products, and avoidance of intramuscular injections.
- A written report of the examination will be sent to the requesting health

care practitioner, who will discuss the results with the patient.

- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include bleeding time, clot retraction, and platelet count.

PLATELET COUNT

SYNONYM/ACRONYM: Thrombocytes.

SPECIMEN: Whole blood from one full lavender-top (EDTA) tube.

REFERENCE VALUE: (Method: Automated, computerized multichannel analyzers that sort and size cells on the basis of either changes in electrical impedance or light pulses as the cells pass in front of a laser)

Age	Platelet Count*	SI Units (Conventional Units × 10^6)	MPV (fL)
1–5 y	217–497 × $10^3/\mu L$ or 217,000–497,000/mm^3 or 217–497 × $10^3/mm^3$	217–497 × 10^9/L	7.2–10.0
Adult	150–450 × $10^3/\mu L$ or 150,000–400,000/mm^3 or 150–400 × $10^3/mm^3$	150–450 × 10^9/L	7.0–10.2

Note: Platelet counts decrease with age.
*Conventional units.
MPV = mean platelet volume.

DESCRIPTION & RATIONALE: *Platelets* are non-nucleated, cytoplasmic, round or oval disks formed by budding off of large, multinucleated cells (megakaryocytes). Platelets have an essential function in coagulation, hemostasis, and blood thrombus formation. *Thrombocytosis* is an increase

in platelet count. In reactive thrombocytosis, the increase is transient and short lived, and it usually does not pose a health risk. One exception may be reactive thrombocytosis occurring after coronary bypass surgery. This circumstance has been identified as an important risk factor for postoperative infarction and thrombosis. The term *thrombocythemia* is used to describe platelet increases associated with chronic myeloproliferative disorders; *thrombocytopenia* is used to describe platelet counts of less than 140 $\times$ $10^3/\mu L$. Decreased platelet counts occur whenever the body's need for platelets exceeds the rate of platelet production; this circumstance will arise if production rate decreases or platelet loss increases. The severity of bleeding is related to platelet count as well as platelet function. Platelet counts can be within normal limits, but the patient may exhibit signs of internal bleeding; this circumstance usually indicates an anomaly in platelet function. Abnormal scatterplot findings by automated cell counters may indicate the need to review a smear of peripheral blood for platelet estimate. Abnormally large or giant platelets may result in underestimation of automated counts by 30% to 50%. A large discrepancy between the automated count and the estimate requires that a manual count be performed.

The significance of platelet sizing is becoming more widely known, as modern cell counters are capable of reporting platelet indexes that are analogous to red blood cell (RBC) indices. Platelet size, reflected by mean platelet volume (MPV), and cellular age are inversely related; that is, younger platelets tend to be larger. An increase in MPV indicates an increase in platelet turnover. Therefore, in a normal patient the platelet count and MPV have an inverse relationship. Abnormal platelet size may also indicate the presence of a disorder. MPV and platelet distribution width (PDW) are both increased in idiopathic thrombocytopenic purpura. MPV is also increased in May-Hegglin anomaly, Bernard-Soulier syndrome, myeloproliferative disorders, hyperthyroidism, and pre-eclampsia. MPV is decreased in Wiskott-Aldrich syndrome, septic thrombocytopenia, and hypersplenism. ■

INDICATIONS:

- Confirm an elevated platelet count (thrombocytosis), which can cause increased clotting
- Confirm a low platelet count (thrombocytopenia), which can be associated with bleeding
- Identify the possible cause of abnormal bleeding, such as epistaxis, hematoma, gingival bleeding, hematuria, and menorrhagia
- Provide screening as part of a complete blood count in a general physical examination, especially upon admission to a health care facility or before surgery

RESULT

Increased in:

- Acute infections
- After exercise (transient)
- Anemias (posthemorrhagic, hemolytic, iron-deficiency)
- Chronic heart disease
- Cirrhosis
- Essential thrombocythemia
- Leukemias (chronic)

- Malignancies (carcinoma, Hodgkin's, lymphomas)
- Pancreatitis (chronic)
- Polycythemia vera
- Rebound recovery from thrombocytopenia
- Rheumatic fever (acute)
- Rheumatoid arthritis
- Splenectomy (2 months postprocedure)
- Surgery (2 weeks postprocedure)
- Trauma
- Tuberculosis
- Ulcerative colitis

Decreased in (as a result of megakaryocytic hypoproliferation):

- Alcohol toxicity
- Aplastic anemia
- Congenital states (Fanconi's syndrome, May Hegglin anomaly, Bernard-Soulier syndrome, Wiskott-Aldrich syndrome, Gaucher's disease, Chédiak-Higashi syndrome)
- Drug toxicity
- Prolonged hypoxia

Decreased in (as a result of ineffective thrombopoiesis):

- Ethanol abuse without malnutrition
- Iron-deficiency anemia
- Megaloblastic anemia (B_{12}/folate deficiency)
- Paroxysmal nocturnal hemoglobinuria
- Thrombopoietin deficiency
- Viral infection

Decreased in (as a result of bone marrow replacement):

- Lymphoma
- Granulomatous infections
- Metastatic carcinoma
- Myelofibrosis

Increased destruction in (as a result of increased loss/consumption):

- Contact with foreign surfaces (dialysis membranes, artificial organs, grafts, prosthetic devices)
- Disseminated intravascular coagulation
- Extensive transfusion
- Severe hemorrhage
- Thrombotic thrombocytopenic purpura
- Uremia

Increased destruction in (as a result of immune reaction):

- Antibody/human leukocyte antigen reactions
- Hemolytic disease of the newborn (target is platelets instead of RBCs)
- Idiopathic thrombocytopenic purpura
- Refractory reaction to platelet transfusion

Increased destruction in (as a result of immune reaction secondary to infection):

- Bacterial infections
- Burns
- Congenital infections (cytomegalovirus, herpes, syphilis, toxoplasmosis)
- Histoplasmosis
- Malaria
- Rocky Mountain spotted fever

Increased destruction in (as a result of other causes):

- Radiation
- Splenomegaly caused by liver disease

CRITICAL VALUES:

Less than 50,000 $\times$ $10^3/\mu L$ (or 50 $\times$ $10^3/mm^3$ or $50,000/mm^3$)

Greater than 1,000 × $10^3/\mu L$ (or 1,000,000/mm^3)

Note and immediately report to the health care practitioner any critically increased or decreased values and related symptoms. Possible interventions for decreased platelet count may include transfusion of platelets.

INTERFERING FACTORS:

- Drugs that may decrease platelet counts include acetohexamide, acetophenazine, amphotericin B, antazoline, anticonvulsants, antimony compounds, apronalide, arsenicals, azathioprine, barbiturates, benzene, busulfan, butaperazine, chlordane, chlorophenothane, chlortetracycline, dactinomycin, dextromethorphan, diethylstilbestrol, ethinamate, ethoxzolamide, floxuridine, hexachlorobenzene, hydantoin derivatives, hydroflumethiazide, hydroxychloroquine, iproniazid, mechlorethamine, mefenamic acid, mepazine, miconazole, mitomycin, nitrofurantoin, novobiocin, nystatin, phenolphthalein, phenothiazine, pipamazine, plicamycin, procarbazine, pyrazolones, streptomycin, sulfonamides, tetracycline, thiabendazole, thiouracil, tolazamide, tolazoline, tolbutamide, trifluoperazine, and urethane.
- Drugs that may increase platelet counts include glucocorticoids.
- X-ray therapy may also decrease platelet counts.
- The results of blood counts may vary depending on the patient's position. Platelet counts can decrease when the patient is recumbent, as a result of hemodilution, and can increase when the patient rises, as a result of hemoconcentration.
- Platelet counts normally increase under a variety of stressors, such as high altitudes or strenuous exercise.
- Platelet counts are normally decreased before menstruation and during pregnancy.
- Leaving the tourniquet in place for longer than 60 seconds can affect the results.
- Traumatic venipunctures may lead to erroneous results as a result of activation of the coagulation sequence.
- Failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.
- Hemolysis or clotted specimens are reasons for rejection.
- Complete blood count should be carefully evaluated after transfusion or acute blood loss because the value may appear to be normal.
- A white blood cell count greater than 100,000/mm^3, severe RBC fragmentation, and extraneous particles in the fluid used to dilute the sample can alter test results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate, diagnose, and monitor bleeding disorders.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic and immune systems, a history of any bleeding disorders, and results of previously performed laboratory tests (especially bleeding time, complete blood count, partial thromboplastin time, prothrombin time, and platelets), surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic and Immune System tables.

- Note any recent procedures that can interfere with test results.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, acetylsalicylic acid, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation. It is recommended that use be discontinued 14 days before dental or surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL lavender-top tube. The specimen should be mixed gently by inverting the tube 10 times. The specimen should be analyzed within 6 hours when stored at room temperature or within 24 hours if stored at refrigerated temperature. If it is anticipated the specimen will not be analyzed within 4 to 6 hours, two blood smears should be made immediately after the venipuncture and submitted with the blood sample.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient to report bleeding from any areas of the skin or mucous membranes.
- Inform the patient with a decreased platelet count of the importance of taking precautions against bruising and bleeding, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of acetylsalicylic acid and similar products, and avoidance of intramuscular injections.
- Inform the patient of the importance of periodic laboratory testing if he or she is taking an anticoagulant.
- *Nutritional considerations:* Instruct patients to consume a variety of foods within the basic food groups, maintain a healthy weight, be physically active, limit salt intake, limit alcohol intake, and be a nonsmoker.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test

results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include antiarrhythmic drugs (quinidine), bleeding time, clot retraction, complete blood count, platelet antibodies, RBC morphology and inclusions, and white blood cell count and differential.

PLETHYSMOGRAPHY

SYNONYM/ACRONYM: Impedance plethysmography, PVR.

AREA OF APPLICATION: Veins, arteries, and lungs.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Plethysmography is a noninvasive diagnostic manometric study used to measure changes in the size of blood vessels by determining volume changes in the blood vessels of the eye, extremities, and neck; or to measure gas volume changes in the lungs.

Arterial plethysmography assesses arterial circulation in an upper or lower limb; it is used to diagnose extremity arteriosclerotic disease and to rule out occlusive disease. The test requires a normal extremity for comparison of results. The test is performed by applying a series of three blood pressure cuffs to the extremity. The amplitude of each pulse wave is then recorded.

Venous plethysmography, done with a series of cuffs, measures changes in venous capacity and outflow (volume and rate of outflow); it is used to diagnose a thrombotic condition that causes obstruction of the major veins of the extremity. When the cuffs are applied to an extremity in patients with venous obstruction, no initial

increase in leg volume is recorded because the venous volume of the leg cannot dissipate quickly.

Body plethysmography measures the total amount (volume) of air within the thorax, whether or not the air is in ventilatory communication with the lung; the elasticity (compliance) of the lungs; and the resistance to airflow in the respiratory tree. It is used in conjunction with pulmonary stress testing and pulmonary function testing.

Impedance plethysmography is widely used to detect acute deep vein thrombosis (DVT) of the leg, but it can also be used in the arm, abdomen, neck, or thorax. Doppler flow studies now are used to identify DVT, but ultrasound studies are less accurate in examinations below the knee. ■

Indications

Arterial Plethysmography:

- Confirm suspected acute arterial embolization
- Detect vascular changes associated with Raynaud's phenomenon and disease
- Determine changes in toe or finger pressures when ankle pressures are elevated as a result of arterial calcifications
- Determine the effect of trauma on the arteries in an extremity
- Determine peripheral small-artery changes (ischemia) caused by diabetes, and differentiate these changes from neuropathy
- Evaluate suspected arterial occlusive disease
- Locate and determine the degree of arterial atherosclerotic obstruction and vessel patency in peripheral atherosclerotic disease, as well as inflammatory changes causing obliteration in the vessels in thromboangiitis obliterans

Venous Plethysmography:

- Detect partial or total venous thrombotic obstruction
- Determine valve competency in conjunction with Doppler ultrasonography in the diagnosis of varicose veins

Body Plethysmography:

- Detect acute pulmonary disorders, such as atelectasis
- Detect or determine the status of chronic obstructive pulmonary disease (COPD), such as emphysema, asthma, or chronic bronchitis
- Detect or determine the status of restrictive pulmonary disease, such as fibrosis
- Detect infectious pulmonary diseases, such as pneumonia
- Determine baseline pulmonary status before pulmonary rehabilitation to determine potential therapeutic benefit
- Differentiate between obstructive and restrictive pulmonary pathology

Impedance Plethysmography:

- Act as a diagnostic screen for patients at risk for DVT
- Detect and evaluate DVT
- Evaluate degree of resolution of DVT after treatment
- Evaluate patients with suspected pulmonary embolism (most pulmonary emboli are complications of DVT in the leg)

Result

Normal Findings:

- Arterial plethysmography:

  Normal arterial pulse waves: steep upslope, more gradual downslope with narrow pointed peaks

  Normal pressure: less than 20 mm Hg systolic difference between the lower and upper extremities;

toe pressure greater than or equal to 80% of ankle pressure, and finger pressure greater than or equal to 80% of wrist pressure

- Venous plethysmography:
  Normal venous blood flow in the extremities
  Venous filling times greater than 20 seconds
- Body plethysmography:
  Thoracic gas volume: 2400 mL
  Compliance: 0.2 L/cm H_2O
  Airway resistance: 0.6 to 2.5 cm H_2O/L per second
- Impedance plethysmography:
  Sharp rise in volume with temporary occlusion
  Rapid venous outflow with release of the occlusion

Abnormal Findings:

- COPD, restrictive lung disease, lung infection, or atelectasis (body plethysmography)
- DVT (arterial, venous, or impedance plethysmography)
- Incompetent valves, thrombosis, or thrombotic obstruction in a major vein in an extremity
- Small-vessel diabetic changes
- Vascular disease (Raynaud's phenomenon)
- Vascular trauma

CRITICAL VALUES: N/A

INTERFERING FACTORS

Arterial Plethysmography:

Factors that may impair results of the examination:

- Cigarette smoking 2 hours before the study, which causes inaccurate results because the nicotine constricts the arteries
- Alcohol consumption
- Low cardiac output
- Shock
- Compression of pelvic veins (tumors or external compression by dressings)
- Environmental temperatures (hot or cold)
- Arterial occlusion proximal to the extremity to be examined, which can prevent blood flow to the limb

Venous Plethysmography:

Factors that may impair results of the examination:

- Low environmental temperature or cold extremity, which constricts the vessels
- High anxiety level or muscle tenseness
- Venous thrombotic occlusion proximal to the extremity to be examined, which can affect blood flow to the limb

Body Plethysmography:

Factors that may impair results of the examination:

- Inability of the patient to follow breathing instructions during the procedure

Impedance Plethysmography:

Factors that may impair results of the examination:

- Movement of the extremity during electrical impedance recording, poor electrode contact, or nonlinear electrical output, which can cause false-positive impedance plethysmography results
- Constricting clothing or bandages

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to measure changes in blood vessel size or changes in gas volume in the lungs.
- Obtain a history of the patient's cardiovascular system, including signs and symptoms of vascular disorders, known or suspected peripheral vascular disease (for arterial and vascular plethysmography), known or suspected diseases of the pulmonary system (for body plethysmography), and signs or symptoms of DVT or circulatory changes (for impedance plethysmography), as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Cardiovascular System table.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Explain the purpose of the test and how the procedure is performed. Address concerns about pain related to the procedure. Explain to the patient that no discomfort will be experienced during the test. For body plethysmography, explain that the procedure measures the amount of air contained in the chest, the elasticity of the lungs, and the occurrence of restrictive breathing in the bronchioles. Explain that there may be some discomfort during insertion of the nasoesophageal catheter if compliance testing is done. Inform the patient that the procedure is generally performed in a specialized area or at the bedside, by a technologist, and usually takes 30 to 60 minutes.
- Assess the patient's ability to comply with directions given for rest, positioning, and activity before and during the procedure.
- For body plethysmography, record the patient's weight, height, and gender. Determine whether the patient is claustrophobic.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during and after the procedure.
- The patient should refrain from smoking for 2 hours prior to the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has refrained from smoking for 2 hours before the procedure.
- Ask the patient to notify medical personnel if he or she has ill effects or unexpected symptoms during the test.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Obtain and record baseline vital signs.
- Observe standard precautions, and follow the general guidelines in Appendix A.

Arterial plethysmography:

- Explain to the patient that cuffs are applied to the extremity to measure and compare blood flow.
- Explain to the patient that it is essential to remain still during the procedure.
- Place the patient in a semi-Fowler position on an examining table or in bed.
- Apply three blood pressure cuffs to the extremity and attach a pulse volume recorder (plethysmograph), which records the amplitude of each pulse wave.
- Inflate the cuffs to 65 mm Hg to measure the pulse waves of each

cuff. When compared with a normal limb, these measurements determine the presence of arterial occlusive disease.

Venous plethysmography:

- Explain to the patient that cuffs are applied to the extremity to measure and compare blood flow.
- Explain to the patient that it is essential to remain still during the procedure.
- Place the patient in a semi-Fowler position on an examining table or in bed.
- Apply two blood pressure cuffs to the extremity, one on the proximal part of the extremity (occlusion cuff) and the other on the distal part of the extremity (recorder cuff). Attach a third cuff to the pulse volume recorder.
- Inflate the recorder cuff to 10 mm Hg, and evaluate the effects of respiration on venous volume: Absence of changes during respirations indicates venous thrombotic occlusion.
- Inflate the occlusion cuff to 50 mm Hg, and record venous volume on the pulse monitor. Deflate the occlusion cuff after the highest volume is recorded in the recorder cuff. A delay in the return to preocclusion volume indicates venous thrombotic occlusion.

Body plethysmography:

- Place the patient in a sitting position on a chair in the body box. Explain to the patient that the cuffs are applied to the extremities to measure and compare blood flow.
- Position a nose clip to prevent breathing through the nose, and connect a mouthpiece to a measuring instrument.
- Ask the patient to breathe through the mouthpiece.
- Close the door to the box, and record the start time of the procedure. At the beginning of the study, ask the patient to pant rapidly and shallowly, without allowing the glottis to close.
- For compliance testing, a double-lumen nasoesophageal catheter is inserted, and the bag is inflated with air. Intraesophageal pressure is recorded during normal breathing.

Impedance plethysmography:

- Explain to the patient that cuffs are applied to the extremity to measure and compare blood flow.
- Place the patient on his or her back with the leg being tested above the heart level.
- Flex the patient's knee slightly, and rotate the hips by shifting weight to the same side as the leg being tested.
- Apply conductive gel and electrodes to the legs, near the cuffs.
- Apply a blood pressure cuff to the thigh.
- Inflate the pressure cuff attached to the thigh temporarily to occlude venous return without interfering with arterial blood flow. Expect the blood volume in the other calf to increase.
- A tracing of changes in electrical impedance occurring during inflation and for 15 seconds after cuff deflation is recorded.
- With DVT, blood volume increases less than expected because the veins are already at capacity.

Post-test:

- Remove conductive gel and electrodes, as applied.
- Instruct the patient to resume usual activity and diet, as directed by the health care practitioner.
- Note severe ischemia, ulcers, and pain of the extremity after arterial, venous, or impedance plethysmography, and handle the extremity gently.
- Note respiratory pattern after body plethysmography, and allow the patient time to resume a normal breathing pattern. Monitor vital signs every 15 minutes until they return to baseline levels.

- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography angiography, echocardiography, magnetic resonance angiography, and ultrasound arterial and venous Doppler of the extremities.

PLEURAL FLUID ANALYSIS

SYNONYM/ACRONYM: Thoracentesis fluid analysis.

SPECIMEN: Pleural fluid (5 mL) collected in a green-top (heparin) tube for amylase, cholesterol, glucose, lactate dehydrogenase (LDH), pH, protein, and triglycerides; lavender-top (EDTA) tube for cell count; sterile containers for microbiology specimens; 200 to 500 mL of fluid in a clear container with anticoagulant for cytology. Ensure that there is an equal amount of fixative and fluid in the container for cytology.

REFERENCE VALUE: (Method: Spectrophotometry for amylase, cholesterol, glucose, LDH, protein, and triglycerides; ion-selective electrode for pH; automated or manual cell count; macroscopic and microscopic examination of cultured microorganisms; microscopic examination of specimen for microbiology and cytology.)

Pleural Fluid	Reference Value
Appearance	Clear
Color	Pale yellow
Amylase	Parallel serum values
Cholesterol	Parallel serum values
Glucose	Parallel serum values
LDH	Less than 200 U/L

Pleural Fluid	Reference Value
Fluid LDH–to–serum LDH ratio	0.6 or less
Protein	3.0 g/dL
Fluid protein–to–serum protein ratio	0.5 or less
Triglycerides	Parallel serum values
pH	7.37–7.43
RBC count	Less than 1000/mm^3
WBC count	Less than 1000/mm^3
Culture	No growth
Gram stain	No organisms seen
Cytology	No abnormal cells seen

LDH = lactate dehydrogenase; RBC = red blood cell; WBC = white blood cell.

DESCRIPTION & RATIONALE: The pleural cavity and organs within it are lined with a protective membrane. The fluid between the membranes is called *serous fluid.* Normally only a small amount of fluid is present because the rates of fluid production and absorption are about the same. Many abnormal conditions can result in the buildup of fluid within the pleural cavity. Specific tests are usually ordered in addition to a common battery of tests used to distinguish a transudate from an exudate. *Transudates* are effusions that form as a result of a systemic disorder that disrupts the regulation of fluid balance, such as a suspected perforation. *Exudates* are caused by conditions involving the tissue of the membrane itself, such as an infection or malignancy. Fluid is withdrawn from the pleural cavity by needle aspiration and tested as listed in the previous and following tables. ■

Characteristic	Transudate	Exudate
Appearance	Clear	Cloudy or turbid
Specific gravity	Less than 1.015	Greater than 1.015
Total protein	Less than 2.5 g/dL	Greater than 3.0 g/dL
Fluid protein–to–serum protein ratio	Less than 0.5	Greater than 0.5
LDH	Parallels serum value	Less than 200 U/L
Fluid LDH–to–serum LDH ratio	Less than 0.6	Greater than 0.6
Fluid cholesterol	Less than 55 mg/dL	Greater than 55 mg/dL
WBC count	Less than 100/mm^3	Greater than 1000/mm^3

LDH = lactate dehydrogenase; WBC = white blood cell.

INDICATIONS:

- Differentiate transudates from exudates
- Evaluate effusion of unknown cause
- Investigate suspected rupture, immune disease, malignancy, or infection

RESULT:

- *Bacterial or tuberculous empyema:* Red blood cell (RBC) count 5000/mm^3, white blood cell (WBC) count 25,000 to 100,000/mm^3 with a predominance of neutrophils, increased fluid protein–

to–serum protein ratio, increased fluid LDH–to–serum LDH ratio, decreased glucose, pH less than 7.3

- *Chylous pleural effusion:* Marked increase in both triglycerides (two to three times serum level) and chylomicrons
- *Effusion caused by pneumonia:* RBC count less than 5000/mm^3, WBC count 5000 to 25,000/mm^3 with a predominance of neutrophils and some eosinophils, increased fluid protein–to–serum protein ratio, increased fluid LDH–to–serum LDH ratio, pH less than 7.4 (and decreased glucose if bacterial pneumonia)
- *Esophageal rupture:* Significantly decreased pH (6.0) and elevated amylase
- *Hemothorax:* Bloody appearance, increased RBC count, elevated hematocrit
- *Malignancy:* RBC count 1000 to 100,000/mm^3, WBC count 5000 to 10,000/mm^3 with a predominance of lymphocytes, abnormal cytology, increased fluid protein–to–serum protein ratio, increased fluid LDH–to–serum LDH ratio, deceased glucose, pH less than 7.3
- *Pancreatitis:* RBC count 1000 to 10,000/mm^3, WBC count 5000 to 20,000/mm^3 with a predominance of neutrophils, pH greater than 7.3, increased fluid protein–to–serum protein ratio, increased fluid LDH–to–serum LDH ratio, increased amylase
- *Pulmonary infarction:* RBC count 10,000 to 100,000/mm^3, WBC count 5000 to 15,000/mm^3 with a predominance of neutrophils, pH greater than 7.3, normal glucose, increased fluid protein–to–serum protein ratio, and increased fluid LDH–to–serum LDH ratio.
- *Pulmonary tuberculosis:* RBC count 10,000/mm^3, WBC count 5000 to 10,000/mm^3 with a predominance of lymphocytes, positive acid-fast bacillus stain and culture, increased protein, decreased glucose, pH less than 7.3
- *Rheumatoid disease:* Normal RBC count, WBC count 1000 to 20,000/mm^3 with a predominance of either lymphocytes or neutrophils, pH less than 7.3, decreased glucose, increased fluid protein–to–serum protein ratio, increased fluid LDH–to–serum LDH ratio, increased immunoglobulins
- *Systemic lupus erythematosus:* Similar findings as with rheumatoid disease, except that glucose is usually not decreased

CRITICAL VALUES:

Note and immediately report to the health care practitioner positive culture results, if ordered, and related symptoms.

INTERFERING FACTORS:

- Bloody fluids may be the result of a traumatic tap.
- Unknown hyperglycemia or hypoglycemia may be misleading in the comparison of fluid and serum glucose levels. Therefore, it is advisable to collect comparative serum samples a few hours before performing thoracentesis.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to classify the type of effusion being produced and identify the cause of its accumulation.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune and reproductive systems, any bleeding disorders, and results of

previously performed laboratory tests (especially bleeding time, complete blood count, partial thromboplastin time, platelets, and prothrombin time), surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Reproductive System tables.

- Note any recent procedures that can interfere with test results.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of medications the patient is taking, including anticoagulant therapy, acetylsalicylic acid, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that it may be necessary to shave the site before the procedure. Discuss with the patient that the requesting health care practitioner may request that a cough suppressant be given before the thoracentesis. Address concerns about pain related to the procedure. Explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to needle insertion through the chest wall into the pleural space. Explain to the patient that any discomfort with the needle insertion will be minimized with local anesthetics and systemic analgesics. Explain that the local anesthetic injection may cause an initial stinging sensation. Meperidine (Demerol) or morphine may be given as a sedative. Inform the patient that the needle insertion is performed under sterile conditions by a health care practitioner specializing in this procedure. The procedure usually takes about 20 minutes to complete.
- Explain that an intravenous (IV) line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food or fluid restrictions, unless by medical direction. The requesting health care practitioner may request that anticoagulants and aspirin be withheld. The amount of days to withhold medication is dependent on the type of anticoagulant.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that anticoagulant therapy has been withheld for the appropriate amount of days prior to the procedure. Notify the health care practitioner if patient anticoagulant therapy has not been withheld.
- Have emergency equipment readily available. Keep resuscitation equipment on hand in the case of respiratory impairment or laryngospasm after the procedure.
- Avoid using morphine sulfate in those with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.
- Have the patient remove clothing and change into a gown for the procedure.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate

collection containers with the corresponding patient demographics, date and time of collection, and site location.

- Record baseline vital signs and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
- Establish an IV line to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.
- Assist the patient into a comfortable sitting or side-lying position.
- Prior to the administration of local anesthesia, shave and cleanse the site with an antiseptic solution, and drape the area with sterile towels. The skin at the injection site is then anesthetized.
- The thoracentesis needle is inserted, and fluid is removed.
- The needle is withdrawn, and pressure is applied to the site with a vaseline gauze. A pressure dressing is applied over the vaseline gauze.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- Place samples in properly labeled specimen container, and promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual medications, as directed by the health care practitioner.
- Monitor vital signs every 15 minutes for the first hour, every 30 minutes for the next 2 hours, every hour for the next 4 hours, and every 4 hours for the next 24 hours. Take the patient's temperature every 4 hours for 24 hours. Monitor intake and output for 24 hours. Notify the health care practitioner if temperature is elevated. Protocols may vary from facility to facility.
- Observe the patient for signs of respiratory distress or skin color changes.
- Observe the thoracentesis site for bleeding, inflammation, or hematoma formation each time vital signs are taken and daily thereafter for several days.
- Observe the patient for hemoptysis, difficulty breathing, cough, air hunger, pain, or absent breathing sounds over the affected area. Report to health care provider.
- Inform the patient that 1 hour or more of bed rest (lying on the unaffected side) is required after the procedure. Elevate the patient's head for comfort.
- Evaluate the patient for symptoms indicating the development of pneumothorax, such as dyspnea, tachypnea, anxiety, decreased breathing sounds, or restlessness. Prepare the patient for a chest x-ray, if ordered, to ensure that a pneumothorax has not occurred as a result of the procedure.
- Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the health care practitioner.
- Administer antibiotics, as ordered, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, if appropriate.
- Reinforce information given by the patient's health care provider regard-

ing further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include bacterial culture, CA 15–3, CA 19–9, CA 125, carcinoembryonic antigen, fungal culture, mycobacterial culture, and viral culture.

PORPHYRINS, URINE

SYNONYMS/ACRONYM: Coproporphyrin, porphobilinogen, urobilinogen, and other porphyrins.

SPECIMEN: Urine (10 mL) from a random or timed specimen collected in a clean, amber-colored plastic collection container with sodium carbonate as a preservative.

REFERENCE VALUE: (Method: Chromatography for uroporphyrins; spectrophotometry for δ-aminolevulinic acid, urobilinogen, and porphobilinogen)

Test	Conventional Units	SI Units
Total porphyrins	Less than 320 μg/24 h	
		(Conventional Units × 1.53)
Coproporphyrin *Tetracarboxyl-coproporphyrin*		
Male	Less than 96 μg/24 h	Less than 147 nmol/24 h
Female	Less than 60 μg/24 h	Less than 92 nmol/24 h
		(Conversion Factor × 1.43)
Uroporphyrins *Pentacarboxyl-porphyrin*		
Male	Less than 4 μg/24 h	Less than 6 nmol/24 h
Female	Less than 3 μg/24 h	Less than 4 nmol/24 h

(*Continued on the following page*)

Test	Conventional Units	SI Units
		(Conventional Units × 1.34)
Hexacarboxyl-porphyrin		
Male	Less than 5 μg/24 h	Less than 7 nmol/24 h
Female	Less than 3 μg/24 h	Less than 4 nmol/24 h
		(Conventional Units × 1.27)
Heptacarboxyl-porphyrin		
Male	Less than 13 μg/24 h	Less than 17 nmol/24 h
Female	Less than 9 μg/24 h	Less than 11 nmol/24 h
		(Conventional Units × 4.42)
Porphobilinogen	Less than 2.0 mg/24 h	Less than 8.8 μmol/24 h
		(Conversion Factor × 1)
Urobilinogen	0.5–4.0 EU/24 h	0.5–4.0 EU/24 h
		(Conventional Units × 7.626)
δ-Aminolevulinic acid	1.5–7.5 mg/24 h	11.4–57.2 μmol/24 h

DESCRIPTION & RATIONALE: Porphyrins are produced during the synthesis of heme. If heme synthesis is disturbed, these precursors accumulate and are excreted in the urine in excessive amounts. Conditions producing increased levels of heme precursors are called *porphyrias.* The two main categories of genetically determined porphyrias are erythropoietic porphyrias, in which major abnormalities occur in red blood cell chemistry, and hepatic porphyrias, in which heme precursors are found in urine and feces. Erythropoietic and hepatic porphyrias are rare. Acquired porphyrias are characterized by greater accumulation of precursors in urine and feces than in red blood cells. Lead poisoning is the most common cause of acquired porphyrias. Porphyrins are reddish fluorescent compounds. Depending on the type of porphyrin present, the urine may be reddish, resembling port wine. Porphobilinogen is excreted as a colorless compound. A color change may occur in an acidic sample containing porphobilinogen if the sample is exposed to air for several hours. ■

INDICATIONS:

- Assist in the diagnosis of congenital or acquired porphyrias, characterized by abdominal pain, tachycardia, emesis, fever, leukocytosis, and neurologic abnormalities
- Detect suspected lead poisoning, as indicated by elevated porphyrins

RESULT

Increased in:

- Acute hepatic porphyrias
- Congenital or acquired porphyrias
- Heavy metal, benzene, or carbon tetrachloride toxicity
- Variegated porphyrias

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase urine porphyrin levels include acriflavine, aminopyrine, ethoxazene, griseofulvin, hexachlorobenzene, oxytetracycline, and sulfonmethane.
- Numerous drugs are suspected as potential initiators of acute attacks, but drugs classified as unsafe for high-risk individuals include aminopyrine, aminoglutethimide, antipyrine, barbiturates, *N*-butylscopolammoniumine bromide, carbamazepine, carbromal, chlorpropamide, danazol, dapsone, diclofenac, diphenylhydantoin, ergot preparations, ethchlorvynol, ethinamate, glutethimide, griseofulvin, *N*-isopropyl meprobamate, mephenytoin, meprobamate, methyprylon, novobiocin, phenylbutazone, primidone, pyrazolone preparations, succinimides, sulfonamide antibiotics, sulfonethylmethane, sulfonmethane, synthetic estrogens and progestins, tolazamide, tolbutamide, trimethadione, and valproic acid.
- Exposure of the specimen to light can falsely decrease values.
- Screening methods are not well standardized and can produce false-negative results.
- Failure to collect all urine and store specimen properly during the 24-hour test period will interfere with results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate porphyrias.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic System table.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
- Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection.

Random specimen (collect in early morning):

Clean-catch specimen:

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling catheter:

- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 minutes before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Timed specimen:

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container's label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.

General:

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's

lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include include δ-aminolevulinic acid, erythrocyte protoporphyrin, and lead.

POSITRON EMISSION TOMOGRAPHY, BRAIN

SYNONYM/ACRONYM: PET scan of the brain.

AREA OF APPLICATION: Brain.

CONTRAST: Intravenous radioactive material (fluorodeoxyglucose [FDG]).

DESCRIPTION & RATIONALE: Positron emission tomography (PET) combines the biochemical properties of nuclear medicine with the accuracy of computed tomography (CT). PET uses positron emissions from specific radionuclides (oxygen, nitrogen, carbon, and fluorine) to produce detailed functional images within the body. After the radionuclide becomes concentrated in the brain, PET images of blood flow or metabolic processes at the cellular level can be obtained. Fluorine-18, in the form of fluorodeoxyglucose (FDG), is one of the more commonly used radionuclides. FDG is a glucose analogue, and because every cell uses glucose, the metabolic activity occurring in neurologic conditions can be measured. There is little localization of FDG in normal tissue, allowing rapid detection of abnormal disease states. The brain uses oxygen and glucose almost exclusively to meet its energy needs, and therefore the brain's metabolism has been studied widely with PET.

The positron radiopharmaceuticals generally have short half-lives, ranging from a few seconds to a few hours, and therefore they must be produced in a cyclotron located near where the test is being done. The PET scanner translates the emissions from the

radioactivity as the positron combines with the negative electrons from the tissues and forms gamma rays that can be detected by the scanner. This information is transmitted to the computer, which determines the location and its distribution and translates the emissions as color-coded images for viewing, quantitative measurements, activity changes in relation to time, and three-dimensional computer-aided analysis. Each radionuclide tracer is designed to measure a specific body process, such as glucose metabolism, blood flow, or brain tissue perfusion. The radionuclide can be administered intravenously or inhaled as a gas. PET has had the greatest clinical impact in patients with epilepsy, dementia, neurodegenerative diseases, inflammation, cerebrovascular disease (indirectly), and brain tumors.

The expense of the study and the limited availability of radiopharmaceuticals limit the use of PET, even though it is more sensitive than traditional nuclear scanning and single-photon emission computed tomography. Changes in reimbursement and the advent of mobile technology have increased the availability of this procedure in the community setting. ■

INDICATIONS:

- Detect Parkinson's disease and Huntington's disease, as evidenced by decreased metabolism
- Determine the effectiveness of therapy, as evidenced by biochemical activity of normal and abnormal tissues
- Determine physiologic changes in psychosis and schizophrenia
- Differentiate between tumor recurrence and radiation necrosis
- Evaluate Alzheimer's disease and differentiate it from other causes of dementia, as evidenced by decreased cerebral flow and metabolism
- Evaluate cranial tumors preoperatively and postoperatively and determine stage and appropriate treatment or procedure
- Identify cerebrovascular accident or aneurysm, as evidenced by decreased blood flow and oxygen use
- Identify focal seizures, as evidenced by decreased metabolism between seizures

RESULT

Normal Findings:

- Normal patterns of tissue metabolism, blood flow, and radionuclide distribution

Abnormal Findings:

- Alzheimer's disease
- Cerebral metastases
- Cerebrovascular accident
- Creutzfeldt-Jakob disease
- Dementia
- Head trauma
- Huntington's disease
- Migraine
- Parkinson's disease
- Schizophrenia
- Seizure disorders
- Tumors

CRITICAL VALUES: N/A

INTERFERING FACTORS

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential

benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Drugs that alter glucose metabolism, such as tranquilizers or insulin, because hypoglycemia can alter PET results
- The use of alcohol, tobacco, or caffeine-containing drinks at least 24 hours before the study, because the effects of these substances would make it difficult to evaluate the patient's true physiologic state (e.g., alcohol is a vasconstrictor and would decrease blood flow to the target organ)
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images

Other considerations:

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- False-positive findings may occur as a result of normal gastrointestinal tract uptake and uptake in areas of infection or inflammation.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiologic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses blood flow to the brain and brain tissue metabolism.
- Obtain a history of the patient's complaints and symptoms, including a list of known allergens.
- Obtain a history of the patient's musculoskeletal system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Musculoskeletal System table.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be

taken into consideration when reviewing results.

- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that radioactive material poses minimal radioactive hazard because of its short half-life and rarely produces side effects. Inform the patient that the procedure is performed in a special department, usually in a radiology suite, by a health care practitioner and support staff, and takes approximately 60 to 120 minutes.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- The patient should restrict food for 4 hours; restrict alcohol, nicotine, or caffeine-containing drinks for 24 hours; and withhold medications for 24 hours before the test. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- Sometimes fluorodeoxyglucose (FDG) examinations are done after blood has been drawn to determine circulating blood glucose levels. If blood glucose levels are high, insulin may be given.

Intratest:

- Ensure that the patient has complied with dietary and medication restrictions and pretesting preparations; assure that food and medications have been restricted as directed prior to the procedure. Ensure the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results
- Record baseline vital signs and assess neurologic status. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- The radionuclide is injected, and imaging is started 30 minutes later. If comparative studies are indicated, additional injections may be needed. Patient is placed in a supine position on the table.
- The patient may be asked to perform different cognitive activities (e.g., reading) to measure changes in brain activity during reasoning or remembering.
- The patient may be blindfolded or asked to use earplugs to decrease auditory and visual stimuli.
- Wear gloves during the radionuclide injection and while handling the patient's urine.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The results are recorded on film or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the health care practitioner.
- Advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- Instruct the patient to drink increased amounts of fluids for 24 to 48 hours to eliminate the radionuclide from the body, unless contraindicated. Educate the patient that radionuclide is eliminated from the body within 6 to 24 hours.
- Instruct the patient to flush the toilet immediately after each voiding following the procedure, and to wash hands meticulously with soap and water after each voiding for 24 hours after the procedure.
- Instruct all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- If a woman who is breast-feeding must have a nuclear scan, she should not breast-feed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- *Nutritional considerations:* A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.
- No other radionuclide tests should be scheduled for 24 to 48 hours after this procedure.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the brain, electroencephalogram, magnetic resonance imaging of the brain, and ultrasound arterial Doppler of the carotids.

POSITRON EMISSION TOMOGRAPHY, HEART

SYNONYMS/ACRONYM: PET scan of the heart.

AREA OF APPLICATION: Heart, chest/thorax, vascular system.

CONTRAST: Intravenous radioactive material (fluorodeoxyglucose [FDG]).

DESCRIPTION & RATIONALE: Positron emission tomography (PET) combines the biochemical properties of nuclear medicine with the accuracy of computed tomography (CT). PET uses positron emissions from specific radionuclides (oxygen, nitrogen, carbon, and fluorine) to produce detailed functional images within the body. After the radionuclide becomes concentrated in the heart, PET images of blood flow or metabolic processes at the cellular level can be obtained. Fluorine-18, in the form of fluorodeoxyglucose (FDG), is one of the more commonly used radionuclides. FDG is a glucose analogue, and because every cell uses glucose, the metabolic activity occurring in heart conditions such as myocardial viability can be measured. There is little localization of FDG in normal tissue, allowing rapid detection of abnormal disease states.

The positron radiopharmaceuticals generally have short half-lives, ranging from a few seconds to a few hours, and therefore they must be produced in a cyclotron located near where the test is being done. The PET scanner translates the emissions from the radioactivity as the positron combines with the negative electrons from the tissues and forms gamma rays that can be detected by the scanner. This information is transmitted to the computer, which determines the location and its distribution and translates the emissions as color-coded images for viewing, quantitative measurements, activity changes in relation to time, and three-dimensional computer-aided analysis. Each radionuclide tracer is designed to measure a specific body process, such as glucose metabolism, blood flow, or tissue perfusion. The radionuclide can be administered intravenously or inhaled as a gas.

The expense of the study and the limited availability of radiopharmaceuticals limit the use of PET, even though it is more sensitive than traditional nuclear scanning and single-photon emission computed tomography. Changes in reimbursement and the advent of mobile technology have increased the availability of this procedure in the community setting. ■

INDICATIONS:

- Assess tissue permeability
- Determine the effects of therapeutic drugs on malfunctioning or diseased tissue
- Determine localization of areas of heart metabolism
- Determine the presence of coronary artery disease, as evidenced by metabolic state during ischemia and after angina
- Determine the size of heart infarcts
- Identify cerebrovascular accident or aneurysm, as evidenced by decreasing blood flow and oxygen use

RESULT

Normal Findings:

- Normal patterns of tissue metabolism, blood flow, and radionuclide distribution

Abnormal Findings:

- Chronic obstructive pulmonary disease
- Decreased blood flow and decreased glucose concentration, indicating necrotic, scarred tissue
- Enlarged left ventricle
- Heart chamber disorder
- Myocardial infarction, indicating increased radionuclide uptake in the myocardium
- Pulmonary edema
- Reduced blood flow but increased glucose concentration, indicating ischemia

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
- Patients with hypersensitivity to the radionuclide

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Drugs that alter glucose metabolism, such as tranquilizers or insulin, because hypoglycemia can alter PET results
- The use of alcohol, tobacco, or caffeine-containing drinks at least 24 hours before the study, because the effects of these substances would make it difficult to evaluate the patient's true physiologic state (e.g., alcohol is a vasconstrictor and would decrease blood flow to the target organ)
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images

Other considerations:

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- False-positive findings may occur as a result of normal gastrointestinal tract uptake and uptake in areas of infection or inflammation.
- Consultation with a health care practitioner should occur before the proce-

dure for radiation safety concerns regarding younger patients or patients who are lactating.

- Risks associated with radiologic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses blood flow to the heart.
- Obtain a history of the patient's complaints and symptoms, including a list of known allergens.
- Obtain a history of the patient's cardiovascular system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Cardiovascular System table.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that radioactive material poses minimal radioactive hazard because of its short half-life and rarely produces side effects. Inform the patient that the procedure is performed in a special department, usually in a radiology or vascular suite, by a health care practitioner and support staff, and takes approximately 60 to 120 minutes.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- The patient should restrict food for 4 hours; restrict alcohol, nicotine, or caffeine-containing drinks for 24 hours; and withhold medications for 24 hours before the test. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- Sometimes fluorodeoxyglucose (FDG) examinations are done after blood has been drawn to determine circulating blood glucose levels. If blood glucose levels are high, insulin may be given.

Intratest:

- Ensure that the patient has complied with dietary and medication restrictions and pretesting preparations; assure that food and medications have been restricted as directed prior to the procedure. Ensure the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- Patients are given a gown, robe, and

foot coverings to wear and instructed to void prior to the procedure.

- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs and assess neurologic status. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- The radionuclide is injected while the patient is in the supine position; imaging is done at periodic intervals, and continuous scanning is done for 1 hour. If comparative studies are indicated, additional injections may be needed.
- Wear gloves during the radionuclide injection and while handling the patient's urine.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The results are recorded on film or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the health care practitioner.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- Instruct the patient to drink increased amounts of fluids for 24 to 48 hours to eliminate the radionuclide from the body, unless contraindicated. Educate the patient that radionuclide is eliminated from the body within 6 to 24 hours.
- Instruct the patient to flush the toilet immediately after each voiding following the procedure, and to wash hands meticulously with soap and water after each voiding for 24 hours after the procedure.
- Instruct all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- If a woman who is breast-feeding must have a nuclear scan, she should not breast-feed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- *Nutritional considerations:* A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.
- No other radionuclide tests should be scheduled for 24 to 48 hours after this procedure.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regard-

ing further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.

- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the thorax, echocardiogram, electrocardiography, magnetic resonance imaging of the chest, and myocardial perfusion scan.

POSITRON EMISSION TOMOGRAPHY, PELVIS

SYNONYM/ACRONYM: PET scan of the pelvis.

AREA OF APPLICATION: Pelvis.

CONTRAST: Intravenous radioactive material (fluorodeoxyglucose [FDG]).

DESCRIPTION & RATIONALE: Positron emission tomography (PET) combines the biochemical properties of nuclear medicine with the accuracy of computed tomography (CT). PET uses positron emissions from specific radionuclides (oxygen, nitrogen, carbon, and fluorine) to produce detailed functional images within the body. After the radionuclide becomes concentrated in the pelvis, PET images of blood flow or metabolic processes at the cellular level can be obtained. Colorectal tumor detection, tumor staging, evaluation of the effects of therapy, detection of recurrent disease, and detection of metastases are the main reasons to do a pelvic PET scan. Fluorine-18, in the form of fluorodeoxyglucose (FDG), is one of the more commonly used radionuclides. FDG is a glucose analogue, and because every cell uses glucose, the metabolic activity occurring in pelvic conditions such as colorectal cancer can be measured. There is little localization of FDG in normal tissue, allowing rapid detection of abnormal disease states.

The positron radiopharmaceuticals generally have short half-lives, ranging from a few seconds to a few hours,

and therefore they must be produced in a cyclotron located near where the test is being done. The PET scanner translates the emissions from the radioactivity as the positron combines with the negative electrons from the tissues and forms gamma rays that can be detected by the scanner. This information is transmitted to the computer, which determines the location and its distribution and translates the emissions as color-coded images for viewing, quantitative measurements, activity changes in relation to time, and three-dimensional computer-aided analysis. Each radionuclide tracer is designed to measure a specific body process, such as glucose metabolism, blood flow, or tissue perfusion.

The expense of the study and the limited availability of radiopharmaceuticals limit the use of PET, even though it is more sensitive than traditional nuclear scanning and single-photon emission computed tomography. Changes in reimbursement and the advent of mobile technology have increased the availability of this procedure in the community setting. ■

INDICATIONS:

- Determine the effects of therapy
- Determine the presence of colorectal cancer
- Determine the presence of metastases of a cancerous tumor
- Determine the recurrence of tumor or cancer
- Identify the site for biopsy

RESULT

Normal Findings:

- Normal patterns of tissue metabolism, blood flow, and radionuclide distribution
- No focal uptake of radionuclide

Abnormal Findings:

- Focal uptake of the radionuclide in pelvis
- Focal uptake in abnormal lymph nodes
- Focal uptake in tumor
- Focal uptake in metastases

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Patients who are very obese, who may exceed the weight limit for the equipment
- Drugs that alter glucose metabolism, such as tranquilizers or insulin, because hypoglycemia can alter PET results
- The use of alcohol, tobacco, or caffeine-containing drinks at least 24 hours before the study, because the effects of these substances would make it difficult to evaluate the patient's true physiologic state (e.g., alcohol is a vasconstrictor and would decrease blood flow to the target organ)
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images

Other considerations:

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- False-positive findings may occur as a result of normal gastrointestinal tract uptake and uptake in areas of infection or inflammation.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiologic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the pelvis and its contents for abnormal organ function.
- Obtain a history of the patient's complaints and symptoms, including a list of known allergens.
- Obtain a history of the patient's gastrointestinal system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Gastrointestinal System table.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Explain the purpose of the test and how the procedure is performed. Reassure the patient that radioactive material poses minimal radioactive hazard because of its short half-life and rarely produces side effects. Inform the patient that the procedure is performed in a special department, usually in a radiology suite, by a health care practitioner and support staff, and takes approximately 30 to 60 minutes.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- The patient should restrict food for 4 hours; restrict alcohol, nicotine, or caffeine-containing drinks for 24 hours; and withhold medications for 24 hours before the test. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- Sometimes fluorodeoxyglucose (FDG) examinations are done after blood has been drawn to determine circulating blood glucose levels. If blood

glucose levels are high, insulin may be given.

Intratest:

- Ensure that the patient has complied with dietary and medication restrictions and pretesting preparations; assure that food and medications have been restricted as directed prior to the procedure. Ensure the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs and assess neurologic status. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- The radionuclide is injected, and imaging is started after a 45-minute delay. Continuous scanning may be done for 1 hour after the patient is placed in the supine position on a scanning table. If comparative studies are indicated, additional injections of radionuclide may be needed.
- If required, the bladder may need to be lavaged via a urinary catheter with 2 L of 0.9% saline solution to remove concentrated radionuclide.
- Wear gloves during the radionuclide injection and while handling the patient's urine.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The results are recorded on film or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the health care practitioner.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- Instruct the patient to drink increased amounts of fluids for 24 to 48 hours to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hours.
- Instruct the patient to flush the toilet immediately after each voiding following the procedure, and to wash hands meticulously with soap and water after each voiding for 24 hours after the procedure.
- Tell all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- If a woman who is breast-feeding must have a nuclear scan, she should not breast-feed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- No other radionuclide tests should be scheduled for 24 to 48 hours after this procedure.
- A written report of the examination

will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.

- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the abdomen; kidney, ureter, and bladder (KUB) study; and magnetic resonance imaging of the abdomen.

POTASSIUM, BLOOD

SYNONYM/ACRONYM: Serum K^+.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Ion-selective electrode)

Serum	Conventional Units	SI Units (Conventional Units × 1)
Newborn	3.7–5.9 mEq/L	3.7–5.9 mmol/L
Infant	4.1–5.3 mEq/L	4.1–5.3 mmol/L
Child	3.4–4.7 mEq/L	3.4–4.7 mmol/L
Adult	3.5–5.0 mEq/L	3.5–5.0 mmol/L

Note: Serum values are 0.1 mmol/L higher than plasma values, and reference ranges should be adjusted accordingly. It is important that serial measurements be collected using the same type of collection container to reduce variability of results from collection to collection.

DESCRIPTION & RATIONALE: Electrolytes dissociate into electrically charged ions when dissolved. Cations, including potassium, carry a positive charge. Body fluids contain approximately equal numbers of anions and cations, although the nature of the ions and their mobility differs between the intracellular and extracellular compartments. Both types of ions affect the electrical and osmolar functions of the body. Electrolyte quantities and the balance among them are controlled by oxygen and carbon dioxide exchange in the lungs; absorption, secretion, and excretion of many substances by the kidneys; and secretion of regulatory hormones by the endocrine glands. Potassium is the most abundant intracellular cation. It is essential for the transmission of electrical impulses in cardiac and skeletal muscle. It also functions in enzyme reactions that transform glucose into energy and amino acids into proteins. Potassium helps maintain acid-base equilibrium, and it has a significant and inverse relationship to pH: A decrease in pH of 0.1 increases the potassium level by 0.6 mEq/L.

Abnormal potassium levels can be caused by a number of contributing factors, which can be categorized as follows: ■

Altered renal excretion: Normally, 80% to 90% of the body's potassium is filtered out through the kidneys each day (the remainder is excreted in sweat and stool); renal disease can result in abnormally high potassium levels.

Altered dietary intake: A severe potassium deficiency can be caused by an inadequate intake of dietary potassium.

Altered cellular metabolism: Damaged red blood cells (RBCs) release potassium into the circulating fluid, resulting in increased potassium levels.

INDICATIONS:

- Assess a known or suspected disorder associated with renal disease, glucose metabolism, trauma, or burns
- Assist in the evaluation of electrolyte imbalances; this test is especially indicated in elderly patients, patients receiving hyperalimentation supplements, patients on hemodialysis, and patients with hypertension
- Evaluate cardiac arrhythmia to determine whether altered potassium levels are contributing to the problem, especially during digitalis therapy, which leads to ventricular irritability
- Evaluate the effects of drug therapy, especially diuretics
- Evaluate the response to treatment for abnormal potassium levels
- Monitor known or suspected acidosis, because potassium moves from RBCs into the extracellular fluid in acidotic states
- Routine screen of electrolytes in acute and chronic illness

RESULT

Increased in:

- Acidosis
- Acute renal failure
- Addison's disease
- Asthma
- Burns
- Chronic interstitial nephritis
- Dehydration
- Dialysis
- Diet (excessive intake of salt substitutes or of potassium salts in medications)

- Excessive theophylline administration
- Exercise
- Hemolysis (massive)
- Hyperventilation
- Hypoaldosteronism
- Insulin deficiency
- Ketoacidosis
- Leukocytosis
- Muscle necrosis
- Near drowning
- Pregnancy
- Prolonged periods of standing
- Tissue trauma
- Transfusion of old banked blood
- Tubular unresponsiveness to aldosterone
- Uremia

Decreased in:

- Alcoholism
- Alkalosis
- Anorexia nervosa
- Bradycardia
- Chronic, excessive licorice ingestion (from licorice root)
- Congestive heart failure
- Crohn's disease
- Cushing's syndrome
- Diet deficient in meat and vegetables
- Excess insulin
- Familial periodic paralysis
- Gastrointestinal loss due to vomiting, diarrhea, nasogastric suction, or intestinal fistula
- Hyperaldosteronism
- Hypertension
- Hypomagnesemia
- Intravenous (IV) therapy with inadequate potassium supplementation
- Laxative abuse
- Malabsorption
- Pica (eating substances of no nutritional value, e.g., clay)
- Renal tubular acidosis
- Stress
- Sweating
- Thyrotoxicosis
- Toxic shock syndrome

CRITICAL VALUES:

Less than 2.5 mmol/L

Greater than 6.5 mmol/L

Note and immediately report to the health care practitioner any critically increased or decreased values and related symptoms, especially symptoms of fluid imbalance.

Symptoms of hyperkalemia include irritability, diarrhea, cramps, oliguria, difficulty speaking, and cardiac arrhythmias (peaked T waves and ventricular fibrillation). Continuous cardiac monitoring is indicated. Administration of sodium bicarbonate or calcium chloride may be requested. If the patient is receiving an IV supplement, verify that the patient is voiding.

Symptoms of hypokalemia include malaise, thirst, polyuria, anorexia, weak pulse, low blood pressure, vomiting, decreased reflexes, and electrocardiographic changes (depressed T waves and ventricular ectopy). Replacement therapy is indicated.

INTERFERING FACTORS:

- Drugs that can cause an increase in potassium levels include dexamethasone, enalapril, mannitol, methicillin, metoprolol, nonsteroidal anti-inflammatory drugs, some drugs with potassium salts, propranolol, spironolactone, and succinylcholine.

- Drugs that can cause a decrease in potassium levels include acetazolamide, acetylsalicylic acid, alanine, albuterol, aldosterone, ammonium chloride, amphotericin B, bicarbonate, bisacodyl, captopril, carbenicillin, cathartics, cisplatin, clorexolone, desoxycorticosterone, dexamethasone, digoxin, diuretics, enalapril, furosemide, hydrocortisone, hydroflumethiazide, laxatives, moxalactam (common when coadministered with amikacin), large doses of any IV penicillin, phenolphthalein (with chronic laxative abuse), phosphates, IV theophylline, thiazides, and triamterene. A number of these medications initially increase the serum potassium level, but they also have a diuretic effect, which promotes potassium loss in the urine except in cases of renal insufficiency.
- Leukocytosis, as seen in leukemia, causes elevated potassium levels.
- False elevations can occur with vigorous pumping of the hand during venipuncture. Hemolysis of the sample and high platelet counts also increase potassium levels, as follows: (1) Because potassium is an intracellular ion and concentrations are approximately 150 times extracellular concentrations, even a slight amount of hemolysis can cause a significant increase in levels. (2) Platelets release potassium during the clotting process, and therefore serum samples collected from patients with elevated platelet counts may produce spuriously high potassium levels. Plasma would be the specimen of choice in patients known to have elevated platelet counts.
- False increases are seen in unprocessed samples left at room temperature because a significant amount of potassium leaks out of the cells within a few hours. Plasma or serum should be separated from cells within 4 hours of collection.
- Storage of unprocessed blood causes potassium levels to increase because a significant amount of potassium leaks out of the cells within a few hours. Plasma or serum should be separated from cells within 4 hours of collection.
- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is present in the IV solution, falsely increasing the result.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assess electrolyte balance.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly. Especially note complaints of weakness and confusion.
- Obtain a history of the patient's cardiovascular, endocrine, gastrointestinal, genitourinary, immune, and respiratory systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Cardiovascular, Endocrine, Gastrointestinal, Genitourinary, Immune, and Respiratory System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that spec-

imen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.

- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement. Instruct patient not to clench and unclench the fist immediately before or during specimen collection.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-, tiger-, or green-top (heparin) tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* There are no recommended dietary allowances established for potassium, but the estimated minimum intake for adults is 200 mEq/d. Potassium is present in all plant and animal cells, making dietary replacement simple to achieve in the potassium-deficient patient.
- Observe the patient for signs and symptoms of fluid volume excess related to excess potassium intake, fluid volume deficit related to active loss, or risk of injury related to an alteration in body chemistry. Symptoms include dehydration, diarrhea, vomiting, or prolonged anorexia. Instruct the patient in electrolyte replacement therapy and changes in dietary intake that affect electrolyte levels.
- Increased potassium levels may be associated with dehydration. Evaluate the patient for signs and symptoms of dehydration. Dehydration is a significant and common finding in geriatric patients and other patients in whom renal function has deteriorated.
- Patients receiving digoxin or diuretics should have potassium levels monitored carefully because cardiac arrhythmias can occur.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include aldosterone, anion gap, antiarrhythmic drugs, arterial/alveolar oxygen ratio, blood gases, calcium, electrolytes, osmolality, potassium urine, and sodium (blood and urine).

POTASSIUM, URINE

SYNONYM/ACRONYM: Urine K^+.

SPECIMEN: Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

REFERENCE VALUE: (Method: Ion-selective electrode)

Age	Conventional Units	SI Units (Conventional Units × 1)
6–10 y		
Male	17–54 mEq/24 h	17–54 mmol/24 h
Female	8–37 mEq/24 h	8–37 mmol/24 h
10–14 y		
Male	22–57 mEq/24 h	22–57 mmol/24 h
Female	18–58 mEq/24 h	18–58 mmol/24 h
Adult	26–123 mEq/24 h	26–123 mmol/24 h

Note: Reference values depend on potassium intake and diurnal variation. Excretion is significantly higher at night.

DESCRIPTION & RATIONALE: Electrolytes dissociate into electrically charged ions when dissolved. Cations, including potassium, carry a positive charge. Body fluids contain approximately equal numbers of anions and cations, although the nature of the ions and their mobility differs between the intracellular and extracellular compartments. Both types of ions affect the electrical and osmolar functions of the body. Electrolyte quantities and the balance among them are controlled by oxygen and carbon dioxide exchange in the lungs; absorption, secretion, and excretion of many substances by the kidneys; and secretion of regulatory hormones by the endocrine glands. Potassium is the most abundant intracellular cation. It is essential for the transmission of electrical impulses in cardiac and skeletal muscle. It also functions in enzyme reactions that transform glucose into energy and amino acids into proteins. Potassium helps maintain acid-base equilibrium, and it has a significant and inverse relationship to pH: A decrease in pH of 0.1 increases the potassium level by 0.6 mEq/L.

Abnormal potassium levels can be caused by a number of contributing factors, which can be categorized as follows:

Altered renal excretion: Normally, 80% to 90% of the body's potassium is filtered out through the kidneys each day (the remainder is excreted in sweat and stool); renal disease can result in abnormally high potassium levels.

Altered dietary intake: A severe potassium deficiency can be caused by an inadequate intake of dietary potassium.

Altered cellular metabolism: Damaged red blood cells (RBCs) release potassium into the circulating fluid, resulting in increased potassium levels.

Regulating electrolyte balance is one of the major functions of the kidneys. In normally functioning kidneys, urine potassium levels increase when serum levels are high and decrease when serum levels are low to maintain homeostasis. The kidneys respond to alkalosis by excreting potassium to retain hydrogen ions and increase acidity. In acidosis, the body excretes hydrogen ions and retains potassium. Analyzing these urinary levels can provide important clues to the functioning of the kidneys and other major organs. Urine potassium tests usually involve timed urine collections over a 12- or 24-hour period. Measurement of random specimens also may be requested. ■

INDICATIONS:

- Determine the potential cause of renal calculi
- Evaluate known or suspected endocrine disorder
- Evaluate known or suspected renal disease
- Evaluate malabsorption disorders

RESULT

Increased in:

- Albright-type renal disease
- Cushing's syndrome
- Diabetic ketoacidosis
- Diuretic therapy
- Hyperaldosteronism
- Starvation (onset)
- Vomiting

Decreased in:

- Addison's disease
- Potassium deficiency (chronic)
- Renal failure with decreased urine flow

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs and substances that can cause an increase in urine potassium levels include acetazolamide, acetylsalicylic acid, ammonium chloride, bendroflumethiazide, carbenoxolone, chlorthalidone, citrates, clopamide, corticosteroids, cortisone, desoxycorticosterone, dexamethasone, diuretics, dopamine, ethacrynic acid, glycyrrhiza, intra-amniotic saline, mefruside, niacinamide, some oral contraceptives, thiazides, triflocin, and viomycin.
- Drugs that can cause a decrease in urine potassium levels include alanine, amiloride, anesthetic agents, cyclosporine, felodipine, levarterenol, and ramipril.
- A dietary deficiency or excess of potassium can lead to spurious results.
- Diuretic therapy with excessive loss of electrolytes into the urine may falsely elevate results.
- All urine voided for the timed collection period must be included in the

collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

- Potassium levels are subject to diurnal variation (output being highest at night), which is why 24-hour collections are recommended.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate electrolyte balance, acid-base balance, and hypokalemia.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine, gastrointestinal, and genitourinary systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine, Gastrointestinal, and Genitourinary System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
- Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

Random specimen (collect in early morning):

Clean-catch specimen:

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.

- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling catheter:

- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 minutes before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Timed specimen:

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container's label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.

General:

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- *Nutritional considerations:* There are no recommended dietary allowances established for potassium, but the estimated minimum intake for adults is 200 mEq/d. Potassium is present in all plant and animal cells, making dietary replacement simple to achieve in the potassium-deficient patient.
- Observe the patient for signs and symptoms of fluid volume excess related to excess potassium intake, fluid volume deficit related to active loss, or risk of injury related to an alteration in body chemistry. Symptoms include dehydration, diarrhea, vomiting, or prolonged anorexia. Instruct the patient in electrolyte replacement therapy and changes in dietary intake that affect electrolyte levels.
- Increased potassium levels may be associated with dehydration. Evaluate the patient for signs and symptoms of dehydration. Dehydration is a significant and common finding in geriatric patients and other patients in whom renal function has deteriorated.
- Patients receiving digoxin or diuretics should have potassium levels monitored carefully because cardiac arrhythmias can occur.
- Increased urine potassium levels may be associated with the forma-

tion of kidney stones. Educate the patient, if appropriate, on the importance of drinking a sufficient amount of water when kidney stones are suspected.

- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include aldosterone, kidney stone analysis, osmolality, blood potassium, renin, and blood and urine sodium.

PREALBUMIN

SYNONYM/ACRONYM: Transthyretin.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Nephelometry)

Age	Conventional Units	SI Units (Conventional Units × 10)
Newborn–1 mo	7.0–39.0 mg/dL	70–390 mg/L
1–6 mo	8.3–34.0 mg/dL	83–340 mg/L
6 mo–4 y	2.0–36.0 mg/dL	20–360 mg/L
5–6 y	12.0–30.0 mg/dL	120–300 mg/L
6 y–adult	12.0–42.0 mg/dL	120–420 mg/L

DESCRIPTION & RATIONALE: Prealbumin is a protein primarily produced by the liver. It is the major transport protein for triiodothyronine and thyroxine. It is also important in the metabolism of retinol-binding pro-

tein, which is needed for transporting vitamin A (retinol). Prealbumin has a short biologic half-life of 2 days. This makes it a good indicator of protein status and an excellent marker for malnutrition. Prealbumin is often measured simultaneously with transferrin and albumin. ■

INDICATIONS: Evaluate nutritional status

RESULT

Increased in:

- Alcoholism
- Chronic renal failure
- Patients receiving steroids

Decreased in:

- Acute-phase inflammatory response
- Diseases of the liver
- Hepatic damage
- Malnutrition
- Tissue necrosis

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase prealbumin levels include anabolic steroids, anticonvulsants, danazol, oral contraceptives, prednisolone, prednisone, and propranolol.
- Drugs that may decrease prealbumin levels include amiodarone and diethylstilbestrol.
- Fasting 4 hours before specimen collection is highly recommended. Reference ranges are often based on fasting populations to provide some level of standardization for comparison. The presence of lipids in the blood may also interfere with the test method; fasting eliminates this potential source of error, especially if the patient has elevated lipid levels.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate nutritional status and assess liver function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine, gastrointestinal, and hepatobiliary systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine, Gastrointestinal, and Hepatobiliary System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- Instruct the patient to fast for 4 hours before specimen collection.
- There are no fluid or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 4 hours prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should

be taken to avoid the use of equipment containing latex.

- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient to resume usual diet, as directed by the health care practitioner.
- *Nutritional considerations:* Nutritional therapy may be indicated for patients with decreased prealbumin levels. Educate the patient, as appropriate, that good dietary sources of complete protein (containing all eight essential amino acids) include meat, fish, eggs, and dairy products; and that good sources of incomplete protein (lacking one or more of the eight essential amino acids) include grains, nuts, legumes, vegetables, and seeds.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include albumin, chloride, ferritin, iron/total iron-binding capacity, potassium, protein, sodium, and transferrin.

PROCTOSIGMOIDOSCOPY

SYNONYMS/ACRONYM: Anoscopy (anal canal), proctoscopy (rectum), sigmoidoscopy (sigmoid colon), flexible fiberoptic sigmoidoscopy, flexible proctosigmoidoscopy.

AREA OF APPLICATION: Anus, rectum, colon.

CONTRAST: Air.

DESCRIPTION & RATIONALE: Proctosigmoidoscopy allows direct visualization of the mucosa of the anal canal (anoscopy), rectum (proctoscopy), and distal sigmoid colon (sigmoidoscopy). The procedure can be performed using a rigid or flexible fiberoptic endoscope, but the flexible instrument is generally preferred. The endoscope is a multichannel device allowing visualization of the mucosal lining of the colon, instillation of air, removal of fluid and foreign objects, obtaining of tissue biopsy specimens, and use of a laser for the destruction of tissue and control of bleeding. The endoscope is advanced approximately 60 cm into the colon. This procedure is commonly used in patients with lower abdominal and perineal pain; changes in bowel habits; rectal prolapse during defecation; or passage of blood, mucus, or pus in the stool. Proctosigmoidoscopy can also be a therapeutic procedure, allowing removal of polyps or hemorrhoids or reduction of a volvulus. Biopsy specimens of suspicious sites may be obtained during the procedure. This procedure is recommended for patients who are more than 50 years old as part of a routine screening for colorectal cancer. ■

INDICATIONS:

- Confirm the diagnosis of diverticular disease
- Confirm the diagnosis of Hirschsprung's disease and colitis in children
- Determine the cause of pain and rectal prolapse during defecation
- Determine the cause of rectal itching, pain, or burning
- Evaluate the cause of blood, pus, or mucus in the stool
- Evaluate postoperative anastomosis of the colon
- Examine the distal colon before barium enema x-ray to obtain improved visualization of the area, and after a barium enema when x-ray findings are inconclusive
- Reduce volvulus of the sigmoid colon
- Remove hemorrhoids by laser therapy
- Screen for and excise polyps
- Screen for colon cancer

RESULT

Normal Findings:

- Normal mucosa of the anal canal, rectum, and sigmoid colon

Abnormal Findings:

- Anal fissure or fistula
- Anorectal abscess
- Benign lesions
- Bleeding sites
- Bowel infection or inflammation
- Crohn's disease
- Diverticula
- Hypertrophic anal papillae
- Internal and external hemorrhoids
- Polyps
- Rectal prolapse
- Tumors
- Ulcerative colitis
- Vascular abnormalities

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with bleeding disorders, especially disorders associated with uremia and cytotoxic chemotherapy
- Patients with cardiac conditions or arrhythmias
- Patients with bowel perforation, acute peritonitis, ischemic bowel necrosis, toxic megacolon, diverticulitis, recent bowel surgery, advanced pregnancy, severe cardiac or pulmonary disease, recent myocardial infarction, known or suspected pulmonary embolus, large abdominal aortic or iliac aneurysm, and coagulation abnormality

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Strictures or other abnormalities preventing passage of the scope
- Barium swallow or upper gastrointestinal (GI) series within the preceding 48 hours
- Severe lower GI bleeding or the presence of feces, barium, blood, or blood clots

Other considerations:

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Use of bowel preparations that include laxatives or enemas should be avoided in pregnant patients or patients with inflammatory bowel disease, unless specifically directed by a health care practitioner.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to examine the rectum and the distal portion of the colon.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal system, as well as results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Gastrointestinal System table.
- Ensure that this procedure is performed before an upper GI study or barium swallow.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, acetylsalicylic acid, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation. It is recommended that use be discontinued 14 days before dental or surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Note intake of oral iron preparations within 1 week before the procedure because these cause black, sticky feces that are difficult to remove with bowel preparation.

- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to insertion of the anoscope. Explain the purpose of the test and how the procedure is performed. Inform the patient that the procedure is performed in a GI lab, usually by a health care practitioner and support staff, and takes approximately 30 to 60 minutes.
- Inform the patient that the urge to defecate may be experienced when the scope is passed. Encourage slow, deep breathing through the mouth to help alleviate the feeling.
- Inform the patient that flatus may be expelled during and after the procedure owing to air that is injected into the scope to improve visualization.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to eat a low-residue diet for several days before the procedure, to consume only clear liquids the evening before the test, and to fast and restrict fluids for 8 hours prior to the procedure.
- Inform the patient that it is important the bowel be cleaned thoroughly so that the physician can visualize the colon. Inform the patient that a laxative and cleansing enema may be needed the day before the procedure, with cleansing enemas on the morning of the procedure, depending on the institution's policy.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that the patient has complied with dietary and fluid restrictions; assure that food and fluid have been restricted for at least 8 hours.
- Ensure that ordered laxative has been administered late in the afternoon of the day before the procedure. Two small-volume enemas are administered 1 hour before the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A. Wear gloves and gown throughout the procedure.
- Place the patient an examination table in the left lateral decubitus position or the knee-chest position and drape with the buttocks exposed. The buttocks are placed at or extending slightly beyond the edge of the examination table or bed, preferably on a special examining table that tilts the patient into the desired position.
- The health care practitioner visually inspects the perianal area and then performs a digital rectal examination with a well-lubricated, gloved finger. A fecal specimen may be obtained from the glove when the finger is removed from the rectum.
- A lubricated anoscope (7 cm in length) is inserted, and the anal canal is inspected (anoscopy). The anoscope is removed, and a lubricated proctoscope (27 cm in length) or flexible sigmoidoscope (35 to 60 cm in length) is inserted.
- The scope is manipulated gently to facilitate passage, and air may be insufflated through the scope to improve visualization. Suction and cotton swabs also are used to remove materials that hinder visualization.
- The patient is instructed to take deep breaths to aid in movement of the scope downward through the ascending colon to the cecum and into the terminal portion of the ileum.

- Examination is done as the scope is gradually withdrawn. Photographs are obtained for future reference.
- At the end of the procedure, the scope is completely withdrawn, and residual lubricant is cleansed from the anal area.
- Place fecal or tissue samples and polyps in properly labeled specimen containers, and promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually, on film, or by automated equipment in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, medication, and activity, as directed by the health care practitioner.
- Monitor for any rectal bleeding. Instruct the patient to expect slight rectal bleeding for 2 days after removal of polyps or biopsy specimens, but that heavy rectal bleeding must be immediately reported to the health care practitioner.
- Emphasize that any abdominal pain, tenderness, or distention; pain on defecation; or fever must be reported to the health care practitioner immediately.
- Inform the patient that any bloating or flatulence is the result of air insufflation.
- Encourage the patient to drink several glasses of water to help replace fluid lost during test preparation.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include barium enema, colonoscopy, computed tomography of the abdomen, and magnetic resonance imaging of the abdomen.

PROGESTERONE

SYNONYM/ACRONYM: N/A.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Immunochemiluminometric assay [ICMA])

Hormonal State	Conventional Units	SI Units (Conventional Units × 3.18)
Adult Male	Less than 0.3–1.2 ng/mL	Less than 0.9–3.8 nmol/L
Adult Female	Less than 0.5 ng/mL	Less than 1.6 nmol/L
Follicular phase	0.2–1.4 ng/mL	0.6–4.4 nmol/L
Luteal phase	3.3–25.6 ng/mL	10.5–81.4 nmol/L
Pregnancy, first trimester	11.2–90.0 ng/mL	35.6–286.2 nmol/L
Pregnancy, second trimester	25.5–89.4 ng/mL	81.1–284.3 nmol/L
Pregnancy, third trimester	48.4–422.5 ng/mL	153.9–1343.6 nmol/L
Postmenopausal period	0.0–0.7 ng/mL	0.0–2.2 nmol/L

DESCRIPTION & RATIONALE: Progesterone is a female sex hormone. Its function is to prepare the uterus for pregnancy and the breasts for lactation. Progesterone testing can be used to confirm that ovulation has occurred and to assess the functioning of the corpus luteum. Serial measurements can be performed to help determine the day of ovulation. ■

INDICATIONS:

- Assist in the diagnosis of luteal-phase defects (performed in conjunction with endometrial biopsy)
- Evaluate patients at risk for early or spontaneous abortion
- Identify patients at risk for ectopic pregnancy and assessment of corpus luteum function
- Monitor patients ovulating during human chorionic gonadotropin (HCG), human menopausal gonadotropin, follicle-stimulating hormone/luteinizing hormone–releasing hormone, or clomiphene induction (serial measurements can assist in pinpointing the day of ovulation)
- Monitor patients receiving progesterone replacement therapy

Result

Increased in:

- Chorioepithelioma of the ovary
- Congenital adrenal hyperplasia
- Hydatidiform mole
- Lipoid ovarian tumor
- Theca lutein cyst

Decreased in:

- Galactorrhea-amenorrhea syndrome
- Primary or secondary hypogonadism
- Short luteal phase syndrome
- Threatened abortion

Critical Values: N/A

Interfering Factors:

- Drugs that may increase progesterone levels include clomiphene, corticotropin, hydroxyprogesterone, ketoconazole, mifepristone, progesterone, tamoxifen, and valproic acid.
- Drugs that may decrease progesterone levels include ampicillin, epostane, goserelin, leuprolide, and prostaglandin $F_{2\alpha}$.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to assess ovarian function, assist in fertility workups, and monitor placental function during pregnancy.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine and reproductive systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine and Reproductive System tables.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.

- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and provide support. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide a nonjudgmental, nonthreatening atmosphere for exploring other options (e.g., adoption). Educate the patient regarding access to counseling services, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include cardiolipin antibodies, estradiol, fetal fibronectin, follicle-stimulating hormone, HCG, luteinizing hormone, and prolactin.

PROLACTIN

SYNONYMS/ACRONYMS: Luteotropic hormone, lactogenic hormone, lactogen, HPRL, PRL.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Specimen should be transported tightly capped and in an ice slurry.

REFERENCE VALUE: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 1)
Prepubertal males and females	3.2–20.0 ng/mL	3.2–20.0 μg/L
Men	2.4–13.8 ng/mL	2.4–13.8 μg/L
Women	3.3–26.7 ng/mL	3.3–26.7 μg/L
Pregnant	5.3–215.3 ng/mL	5.3–215.3 μg/L
Postmenopausal	2.4–24.0 ng/mL	2.4–24.0 μg/L

DESCRIPTION & RATIONALE: Prolactin is secreted by the pituitary gland. It is unique among hormones in that it responds to inhibition by the hypothalamus rather than to stimulation. The only known function of prolactin is to induce milk production in female breasts that are already stimulated by high estrogen levels. When milk production is established, lactation can continue without elevated prolactin levels. Prolactin levels rise late in pregnancy, peak with the initiation of lactation, and surge each time a woman breast-feeds. The function of prolactin in males is unknown. ■

INDICATIONS:

- Assist in the diagnosis of primary hypothyroidism, as indicated by elevated levels
- Assist in the diagnosis of suspected tumor involving the lungs or kidneys (elevated levels indicating ectopic prolactin production)
- Evaluate failure of lactation in the postpartum period
- Evaluate sexual dysfunction of unknown cause in men and women
- Evaluate suspected postpartum hypophyseal infarction (Sheehan's syndrome), as indicated by decreased levels

RESULT

Increased in:

- Adrenal insufficiency
- Amenorrhea
- Anorexia nervosa
- Breastfeeding
- Chiari-Frommel and Argonz–Del Castillo syndromes
- Chest wall injury
- Chronic renal failure
- Ectopic prolactin-secreting tumors (e.g., lung, kidney)
- Galactorrhea
- Hypothalamic and pituitary disorders
- Hypothyroidism (primary)
- Insulin-induced hypoglycemia
- Liver failure
- Pituitary tumor
- Polycystic ovary (Stein-Leventhal) syndrome
- Pregnancy
- Surgery (pituitary stalk section)

Decreased in:

- Sheehan's syndrome

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs and hormones that may increase prolactin levels include amitriptyline, amoxapine, arginine, azosemide, benserazide, butaperazine, butorphanol, carbidopa, chlorophenylpiperazine, chlorpromazine, cimetidine, clomipramine, desipramine, diethylstilbestrol, β-endorphin, enflurane, fenfluramine, fenoldopam, flunarizine, fluphenazine, growth hormone–releasing hormone, imipramine, insulin, interferon-β, labetalol, loxapine, megestrol, mestranol, methyldopa, metoclopramide, molindone, morphine, nitrous oxide, oral contraceptives, oxcarbazepine, parathyroid hormone, pentagastrin, perphenazine, phenothiazines, phenytoin, pimozide, prochlorperazine, promazine, ranitidine, remoxipride, reserpine, sulpiride, sultopride, thiethylperazine, thioridazine, thiothixene, thyrotropin-releasing hormone, trifluoperazine, trimipramine, tumor necrosis factor, veralipride, verapamil, and zometapine.
- Drugs and hormones that may decrease prolactin levels include anticonvul-

sants, apomorphine, bromocriptine, cabergoline, calcitonin, cyclosporine, dexamethasone, dopamine, D-Trp-6-LHRH, levodopa, metoclopramide, morphine, nifedipine, octreotide, pergolide, ranitidine, rifampin, ritanserin, ropinirole, secretin, thyroid hormones, and terguride.

- Episodic elevations can occur in response to sleep, stress, exercise, hypoglycemia, and breast-feeding.
- Venipuncture can cause falsely elevated levels.
- Prolactin secretion is subject to diurnal variation, with highest levels occurring in the morning.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to evaluate lactation disorders and identify the presence of prolactin-secreting tumors.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine and reproductive systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine and Reproductive System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Specimen collection should occur between 8 and 10 a.m. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- The patient should fast for 12 hours before specimen collection.
- There are no fluid or medication restrictions, unless by medical direction.
- Prepare an ice slurry in a cup or plastic bag to have on hand for immediate transport of the specimen to the laboratory.

Intratest:

- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 12 hours prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis. The specimen should be placed in an ice slurry immediately after collection. Information on the specimen label can be protected

from water in the ice slurry if the specimen is first placed in a protective plastic bag.

- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient to resume usual diet, as directed by the health care practitioner.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include dehydroepiandrosterone, estradiol, follicle-stimulating hormone, human chorionic gonadotropin, and luteinizing hormone.

PROSTATE-SPECIFIC ANTIGEN

SYNONYM/ACRONYM: PSA.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Immunoassay)

Sex	Conventional Units	SI Units (Conventional Units × 1)
Male	Less than 4 ng/mL	Less than 4 μg/L
Female	Less than 0.5 ng/mL	Less than 0.5 μg/L

DESCRIPTION & RATIONALE: Prostate-specific antigen (PSA) is produced exclusively by the epithelial cells of the prostate, periurethral, and perirectal glands. Used in conjunction with the digital rectal examination,

PSA is a useful test for monitoring adenocarcinoma of the prostate. PSA circulates in both free and bound (complexed) forms. A low ratio of free to complexed PSA (i.e., less than 10%) is suggestive of prostate cancer; a ratio of greater than 30% is rarely associated with prostate cancer. Serial measurements are often performed before and after surgery. *Important note:* When following patients using serial testing, use the same method of measurement consistently. ■

INDICATIONS:

- Evaluate the effectiveness of treatment for prostate cancer (prostatectomy): Levels decrease if treatment is effective; rising levels are associated with recurrence and a poor prognosis.
- Investigate or evaluate an enlarged prostate gland, especially if prostate cancer is suspected.
- Stage prostate cancer.

RESULT

Increased in:

- Benign prostatic hypertrophy
- Prostate cancer
- Prostatic infarct
- Urinary retention

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that decrease PSA levels include buserelin, finasteride, and flutamide.
- There is growing evidence that rectal palpation does not cause elevated PSA. However, increases can occur due to prostatic needle biopsy, cytoscopy, or prostatic infarction.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to monitor status of prostate cancer and response to therapy.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's genitourinary, immune, and reproductive systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Genitourinary, Immune, and Reproductive System tables.
- Note any recent procedures that can interfere with test results.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the

patient to breathe normally and to avoid unnecessary movement.

- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and offer support. Counsel the patient, as appropriate, that sexual dysfunction related to altered body function, drugs, or radiation may occur. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include biopsy of the prostate and prostatic acid phosphatase.

PROTEIN, BLOOD, TOTAL AND FRACTIONS

SYNONYMS/ACRONYMS: TP, SPEP (fractions include albumin, α_1-globulin, α_2-globulin, β-globulin, and γ-globulin).

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Spectrophotometry for total protein, electrophoresis for protein fractions)

Total Protein

Age	Conventional Units	SI Units (Conversion Factor × 10)
Newborn–5 d	3.8–6.2 g/dL	38–62 g/L
1–3 y	5.9–7.0 g/dL	59–70 g/L
4–6 y	5.9–7.8 g/dL	59–78 g/L
7–9 y	6.2–8.1 g/dL	62–81 g/L
10–19 y	6.3–8.6 g/dL	63–86 g/L
Adult	6.0–8.0 g/dL	60–80 g/L

Protein Fractions

	Conventional Units	SI Units (Conversion Factor × 10)
Albumin	3.4–4.8 g/dL	34–48 g/L
α_1-Globulin	0.2–0.4 g/dL	2–4 g/L
α_2-Globulin	0.4–0.8 g/dL	4–8 g/L
β-Globulin	0.5–1.0 g/dL	5–10 g/L
γ-Globulin	0.6–1.2 g/dL	6–12 g/L

DESCRIPTION & RATIONALE: Protein is essential to all physiologic functions. Proteins consist of amino acids, the building blocks of blood and body tissues. Protein is also required for the regulation of metabolic processes, immunity, and proper water balance. Total protein includes albumin and globulins. α_1-Globulin includes α_1-antitrypsin, α_1-fetoprotein, α_1-acid glycoprotein, α_1-antichymotrypsin, inter-α_1-trypsin inhibitor, high-density lipoproteins, and group-specific component (vitamin D–binding protein). α_2-Globulin includes haptoglobin, ceruloplasmin, and α_2-macroglobulin. β-Globulin includes transferrin, hemopexin, very-low-density lipoproteins, low-density lipoproteins, β_2-microglobulin, fibrinogen, complement, and C-reactive protein. γ-Globulin includes immunoglobulin (Ig) G, IgA, IgM, IgD, and IgE. After an acute infection or trauma, levels of many of the liver-derived proteins increase, whereas albumin level decreases; these conditions may not reflect an abnormal total protein determination. ■

INDICATIONS:

- Evaluation of edema, as seen in patients with low total protein and low albumin levels
- Evaluation of nutritional status

RESULT

Increased:

- α_1-Globulin proteins in acute and chronic inflammatory diseases
- α_2-Globulin proteins occasionally in diabetes, pancreatitis, and hemolysis

- β-Globulin proteins in hyperlipoproteinemias and monoclonal gammopathies
- γ-Globulin proteins in chronic liver diseases, chronic infections, autoimmune disorders, hepatitis, cirrhosis, and lymphoproliferative disorders
- Total protein:
  Dehydration
  Monoclonal and polyclonal gammopathies
  Myeloma
  Sarcoidosis
  Some types of chronic liver disease
  Tropical diseases (e.g., leprosy)
  Waldenström's macroglobulinemia

Decreased:

- α_1-Globulin proteins in hereditary deficiency
- α_2-Globulin proteins in nephrotic syndrome, malignancies, numerous subacute and chronic inflammatory disorders, and recovery stage of severe burns
- β-Globulin proteins in hypo-β-lipoproteinemias and IgA deficiency
- γ-Globulin proteins in immune deficiency or suppression
- Total protein
  Administration of intravenous fluids
  Burns
  Chronic alcoholism
  Chronic ulcerative colitis
  Cirrhosis
  Crohn's disease
  Glomerulonephritis
  Heart failure
  Hyperthyroidism
  Malabsorption
  Malnutrition
  Neoplasms
  Nephrotic syndrome
  Pregnancy
  Prolonged immobilization
  Protein-losing enteropathies
  Severe skin disease
  Starvation

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase protein levels include amino acids (if given intravenously), anabolic steroids, angiotensin, anticonvulsants, carbenicillin, corticosteroids, corticotropin, digitalis, furosemide, insulin, isotretinoin, levonorgestrel, oral contraceptives, progesterone, radiographic agents, and thyroid agents.
- Drugs and substances that may decrease protein levels include acetylsalicylic acid, arginine, benzene, carvedilol, citrates, floxuridine, laxatives, mercury compounds, oral contraceptives, pentastarch, phosgene, pyrazinamide, rifampin, trimethadione, and valproic acid.
- Values are significantly lower (5% to 10%) in recumbent patients.
- Hemolysis can falsely elevate results.
- Venous stasis can falsely elevate results; the tourniquet should not be left on the arm for longer than 60 seconds.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to evaluate nutritional status; abnormal values are found in numerous conditions and diseases.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal, hepatobiliary, and immune systems, as well as results

of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Gastrointestinal, Hepatobiliary, and Immune System tables.

- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Educate the patient, as appropriate, that good dietary sources of complete protein (containing all eight essential amino acids) include meat, fish, eggs, and dairy products; and that good sources of incomplete protein (lacking one or more of the eight essential amino acids) include grains, nuts, legumes, vegetables, and seeds.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include albumin, complete blood count, IgA, IgG, IgM, blood and urine immunofixation electrophoresis, urine protein, and urine protein electrophoresis.

PROTEIN C

SYNONYMS/ACRONYM: Protein C antigen, protein C functional.

SPECIMEN: Plasma (1 mL) collected in blue-top (sodium citrate) tube.

REFERENCE VALUE: (Method: Chromogenic) 70% to 140% activity (0.7 to 1.4 U/mL). Values are significantly reduced in children (0.4 to 1.1 U/mL) because of liver immaturity.

DESCRIPTION & RATIONALE: Protein C is a vitamin K–dependent protein that originates in the liver and circulates in plasma. Protein C activation occurs on thrombomodulin receptors on the endothelial cell surface. Thrombin bound to thrombomodulin receptors preferentially activates protein C. Freely circulating thrombin mainly converts fibrinogen to fibrin. Other steps in the activation process require calcium and protein S cofactor binding (see monographs titled "Protein S" and "Fibrinogen"). Activated protein C exhibits potent anticoagulant effects by degrading activated factors V and VIII. There are two types of protein C deficiency:

Type I: Decreased antigen and function, detected by functional and antigenic assays

Type II: Normal antigen but decreased function, detected only by a functional assay

Functional assays are recommended for initial evaluation because of their greater sensitivity. ■

INDICATIONS:

- Differentiate inherited deficiency from acquired deficiency
- Investigate the mechanism of idiopathic venous thrombosis

RESULT

Increased in: N/A

Decreased in:

- Congenital deficiency
- Liver disease
- Oral anticoagulant therapy

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase protein C levels include desmopressin and oral contraceptives.
- Drugs that may decrease protein C levels include coumarin and warfarin (Coumadin).
- Placement of tourniquet for longer than 1 minute can result in venous stasis and changes in the concentration of plasma proteins to be measured. Platelet activation may also occur under these conditions, causing erroneous results.
- Vascular injury during phlebotomy can activate platelets and coagulation factors, causing erroneous results.

- Hemolyzed specimens must be rejected because hemolysis is an indication of platelet and coagulation factor activation.
- Incompletely filled tubes contaminated with heparin or clotted specimens must be rejected.
- Icteric or lipemic specimens interfere with optical testing methods, producing erroneous results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assess anticoagulant function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic and hepatobiliary systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic and Hepatobiliary System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture, and collect the specimen in a 5-mL blue-top tube. *Important note:* Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It is important to inquire from the laboratory which concentration it recommends, because each concentration will have its own specific reference range.
- When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and red-top tubes. When coagulation testing is the only work to be done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with tissue thromboplastin, which can falsely decrease values.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation

for processed and unprocessed specimens stored in unopened tubes is that testing should be completed within 1 to 4 hours of collection.

- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include anticardiolipin antibody, antithrombin III, complete blood count, factor V, fibrin degradation products, fibrinogen, lupus anticoagulant, and protein S.

PROTEIN S

SYNONYMS/ACRONYM: Protein S antigen, protein S functional.

SPECIMEN: Plasma (1 mL) collected in blue-top (sodium citrate) tube.

REFERENCE VALUE: (Method: Clot detection)

	Conventional Units	SI Units (Conventional Units × .01)
Total proteins	70–140% activity	0.7–1.4 U/mL
Free proteins	60–120% activity	0.6–1.2 U/mL

Note: The low end of "normal" is lower in children younger than age 16 years because of the immaturity of the liver.

DESCRIPTION & RATIONALE: Protein S is a vitamin K–dependent protein that originates in the liver and circulates in plasma. It is a cofactor required for the activation of protein C (see monographs titled "Protein C"

and "Fibrinogen"). Protein S exists in two forms, free (biologically active) and bound. Approximately 40% of protein S circulates in the free form; the remainder is bound and is functionally inactive. There are two types of protein S deficiency:

Type I: Decreased antigen and function, detected by functional and antigenic assays

Type II: Normal antigen but decreased function, detected only by a functional assay

Functional assays are recommended for initial evaluation because of their greater sensitivity. ■

INDICATIONS: Investigate the cause of hypercoagulable states

RESULT

Increased in: N/A

Decreased in:

- Chronic renal failure due to hypertension
- Congenital deficiency
- Coumarin-induced skin necrosis
- Diabetic neuropathy
- Disseminated intravascular coagulation
- Liver disease
- Oral anticoagulant therapy

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may decrease protein S levels include coumarin, oral contraceptives, and warfarin (Coumadin).
- Placement of tourniquet for longer than 1 minute can result in venous stasis and changes in the concentration of plasma proteins to be measured. Platelet activation may also occur under these conditions, causing erroneous results.
- Vascular injury during phlebotomy can activate platelets and coagulation factors, causing erroneous results.
- Hemolyzed specimens must be rejected because hemolysis is an indication of platelet and coagulation factor activation.
- Incompletely filled tubes contaminated with heparin or clotted specimens must be rejected.
- Icteric or lipemic specimens interfere with optical testing methods, producing erroneous results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assess anticoagulant function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic and hepatobiliary systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic and Hepatobiliary System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.

- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture, and collect the specimen in a 5-mL blue-top tube. *Important note:* Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It is important to inquire from the laboratory which concentration it recommends, because each concentration will have its own specific reference range.
- When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and red-top tubes. When coagulation testing is the only work to be done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with tissue thromboplastin, which can falsely decrease values.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis. The CLIS recommendation for processed and unprocessed specimens stored in unopened tubes is that testing should be completed within 1 to 4 hours of collection.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include anticardiolipin antibody, antithrombin III, complete blood count, fibrin degradation products, fibrinogen, lupus anticoagulant, and protein C.

PROTEIN, URINE: TOTAL QUANTITATIVE AND FRACTIONS

SYNONYM/ACRONYM: None.

SPECIMEN: Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

REFERENCE VALUE: (Method: Spectrophotometry for total protein, electrophoresis for protein fractions)

	Conventional Units	SI Units (Conventional Units × 0.001)
Total protein	10–140 mg/24 h	0.01–0.14 g/24 h

Electrophoresis for fractionation is qualitative: No monoclonal gammopathy detected. (Urine protein electrophoresis should be ordered along with serum protein electrophoresis.)

DESCRIPTION & RATIONALE: Most proteins, with the exception of the immunoglobulins, are synthesized and catabolized in the liver, where they are broken down into amino acids. The amino acids are converted to ammonia and ketoacids. Ammonia is converted to urea via the urea cycle. Urea is excreted in the urine. ■

INDICATIONS:

- Assist in the detection of Bence Jones proteins (light chains)
- Assist in the diagnosis of myeloma, Waldenström's macroglobulinemia, lymphoma, and amyloidosis
- Evaluate kidney function

RESULT

Increased in:

- Diabetic nephropathy
- Fanconi's syndrome
- Heavy metal poisoning
- Malignancies of the urinary tract
- Monoclonal gammopathies
- Multiple myeloma
- Nephrotic syndrome
- Other myeloproliferative and lymphoproliferative disorders
- Postexercise period
- Sarcoidosis
- Sickle cell disease
- Urinary tract infections

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs and substances that may increase urine protein levels include acetaminophen, aminosalicylic acid, amphotericin B, ampicillin, antimony compounds, antipyrine, arsenicals, ascorbic acid, bacitracin, bismuth subsalicylate, bromate, capreomycin, captopril, carbamazepine, carbarsone, carbenoxolone, carbutamide, cephaloglycin, cephaloridine, chlorpromazine, chlorpropamide, chlorthalidone, chrysarobin, colistimethate, colistin, corticosteroids, cyclosporine, demeclocycline, 1,2 diaminopropane, diatrizoic acid, dihydrotachysterol, doxycycline, enalapril, gentamicin, gold, hydrogen sulfide, iodoalphionic acid, iodopyracet, iopanoic acid, iophenoxic acid, ipodate, kanamycin, corn oil (Lipomul), lithium, mefenamic acid, melarsonyl, melarsoprol, mercury compounds, methicillin, methylbromide, meziocillin, mitomycin, nafcillin, naphthalene, neomycin, nonsteroidal anti-inflammatory drugs, oxacillin, paraldehyde, penicillamine, penicillin, phenolphthalein, phenols, phensuximide, phosphorus, picric acid, piperacillin, plicamycin, polymyxin, probenecid, promazine, pyrazolones, quaternary ammonium compounds, radiographic agents, rifampin, sodium bicarbonate, streptokinase, sulfisoxazole, suramin, tetracyclines, thallium, thiosemicarbazones, tolbutamide, tolmetin, triethylenemelamine, and vitamin D.
- Drugs that may decrease urine protein levels include captopril, cyclosporine, diltiazem, enalapril, fosinopril, interferon, lisinopril, prednisolone, and quinapril.
- All urine voided for the timed collection period must be included in the collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to identify the underlying cause for proteinuria.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's genitourinary and immune systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Genitourinary and Immune System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
- Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory col-

lection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

Random specimen (collect in early morning):

Clean-catch specimen:

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling catheter:

- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 minutes before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Timed specimen:

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than the recorded output, some urine may have been discarded, invalidating the test.
- Include on the collection container's label the amount of urine collected and test start and stop times.

General:

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall

and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include glucose, glycated hemoglobin, blood and urine immunofixation electrophoresis, microalbumin, blood and urine osmolality, blood protein and fractions, and urinalysis.

PROTHROMBIN TIME AND INTERNATIONAL NORMALIZED RATIO

SYNONYM/ACRONYM: Protime, PT.

SPECIMEN: Plasma (1 mL) collected in a completely filled blue-top (sodium citrate) tube.

REFERENCE VALUE: (Method: Clot detection) 10 to 13 seconds.

International Normalized Ratio (INR) = Less than 2.0 for patients not receiving anticoagulation therapy, 2.0 to 3.0 for patients receiving treatment for venous thrombosis, pulmonary embolism, and valvular heart disease.

INR = 2.5 to 3.5 for patients with mechanical heart valves and/or receiving treatment for recurrent systemic embolism.

DESCRIPTION & RATIONALE: Prothrombin time (PT) is a coagulation test performed to measure the time it takes for a firm fibrin clot to form after tissue thromboplastin (factor III) and calcium are added to the sample. It is used to evaluate the extrinsic pathway of the coagulation sequence

in patients receiving oral warfarin or coumarin-type anticoagulants. Prothrombin is a vitamin K–dependent protein produced by the liver; measurement is reported as time in seconds or percentage of normal activity.

The goal of long-term anticoagulation therapy is to achieve a balance between in vivo thrombus formation and hemorrhage. It is a delicate clinical balance—and due to differences in instruments and reagents there is a wide variation in PT results between laboratories. Worldwide concern for the need to provide more consistency in monitoring patients receiving anticoagulant therapy led to the development of an international committee. In the early 1980s, manufacturers of instruments and reagents began comparing their measurement systems with a single reference material provided by the World Health Organization (WHO). The international effort successfully developed an algorithm to provide comparable PT values regardless of differences in laboratory methodology. Reagent and instrument manufacturers compare their results to the WHO reference and derive a factor called an International Sensitivity Index (ISI) that is applied to a mathematical formula to standardize the results. Laboratories convert their PT values into an International Normalized Ratio (INR) by using the following formula:

$$\text{INR} = (\text{patient PT result}/\text{normal patient average})^{(\text{ISI})}$$

PT evaluation can now be based on an INR using a standardized thromboplastin reagent to assist in making decisions regarding oral anticoagulation therapy.

Some inferences of factor deficiency can be made by comparison of results obtained from the activated partial thromboplastin time (APTT) and PT tests. A normal APTT with a prolonged PT can occur only with factor VII deficiency. A prolonged APTT with a normal PT could indicate a deficiency in factors XII, XI, IX, and VIII as well as VIII:C (von Willebrand factor). Factor deficiencies can also be identified by correction or substitution studies using normal serum. These studies are easy to perform and are accomplished by adding plasma from a normal patient to a sample from a suspected factor-deficient patient. When the PT is repeated and corrected, or within the reference range, it can be assumed that the prolonged PT is due to a factor deficiency (see monograph titled "Coagulation Factors"). ■

INDICATIONS:

- Differentiate between deficiencies of clotting factors II, V, VII, and X, which prolong the PT; and congenital coagulation disorders, such as hemophilia A (factor VIII) and hemophilia B (factor IX), which do not alter the PT
- Evaluate the response to anticoagulant therapy with coumarin derivatives and determine dosage required to achieve therapeutic results
- Identify individuals who may be prone to bleeding during surgical, obstetric, dental, or invasive diagnostic procedures
- Identify the possible cause of abnormal bleeding, such as epistaxis, hematoma, gingival bleeding, hematuria, and menorrhagia
- Monitor the effects of conditions such as liver disease, protein deficiency, and fat malabsorption on hemostasis

- Screen for prothrombin deficiency
- Screen for vitamin K deficiency

Result

Increased in:

- Afibrinogenemia, dysfibrinogenemia, or hypofibrinogenemia
- Biliary obstruction
- Disseminated intravascular coagulation
- Hereditary deficiencies of factors II, V, VII, and X
- Intravascular coagulation
- Liver disease (cirrhosis)
- Poor fat absorption (tropical sprue, celiac disease, chronic diarrhea)
- Presence of circulating anticoagulant
- Systemic lupus erythematosus
- Vitamin K deficiency

Decreased in:

- Ovarian hyperfunction
- Regional enteritis or ileitis

Critical values:

INR:

Greater than 3 (in patients on anticoagulant therapy)

Prothrombin time:

Greater than 20 seconds (in patients not on anticoagulant therapy)

Three times normal control (in patients on anticoagulant therapy)

Note and immediately report to the health care practitioner any critically increased values and related symptoms. Important signs to note are prolonged bleeding from cuts or gums, hematoma at a puncture site, hemorrhage, blood in the stool, persistent epistaxis, heavy or prolonged menstrual flow, and shock. Monitor vital signs, unusual ecchymosis, occult blood, severe headache, unusual dizziness, and neurologic changes until PT is within normal range. Intramuscular administration of vitamin K, an anticoagulant reversal agent, may be requested by the health care practitioner.

Interfering factors:

- Drugs that may increase the PT in patients receiving anticoagulation therapy include acetaminophen, acetylsalicylic acid, amiodarone, anabolic steroids, anisindione, anistreplase, antibiotics, antipyrine, carbenicillin, cathartics, chlorthalidone, cholestyramine, clofibrate, corticotropin, demeclocycline, dextrothyroxine, diazoxide, diflunisal, diuretics, doxycycline, erythromycin, glucagon, hydroxyzine, indomethacin, laxatives, mercaptopurine, miconazole, nalidixic acid, neomycin, niacin, oxyphenbutazone, phenytoin, quinine, sulfachlorpyridazine, and thyroxine.
- Drugs that may decrease the PT in patients receiving anticoagulation therapy include amobarbital, anabolic steroids, antacids, antihistamines, barbiturates, carbamazepine, chloral hydrate, chlordane, colchicine, corticosteroids, diuretics, oral contraceptives, penicillin, primidone, rifampin, simethicone, spironolactone, tolbutamide, and vitamin K.
- Traumatic venipunctures can activate the coagulation sequence by contaminating the sample with tissue thromboplastin, and producing falsely shortened PT.
- Failure to fill the tube sufficiently to yield proper blood-to-anticoagulant ratio may cause a falsely lengthened PT; an incompletely filled tube is reason for specimen rejection.

- Excessive agitation causing sample hemolysis can falsely shorten the PT because the hemolyzed cells activate plasma-clotting factors.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate the coagulation system and monitor anticoagulation therapy.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular, hematopoietic, and hepatobiliary systems, any bleeding disorders, and results of previously performed laboratory tests (especially bleeding time, complete blood count, partial thromboplastin time, PT, and platelets), surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Cardiovascular, Hematopoietic, and Hepatobiliary System tables.
- Obtain a list of medications the patient is taking, including anticoagulant therapy, acetylsalicylic acid, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). Note the last time and dose of medication taken. It is recommended that use be discontinued 14 days before dental or surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture, and collect the specimen in a 5-mL blue-top tube. Fill tube completely. *Important note:* Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It is important to inquire from the laboratory which concentration it recommends, because each concentration will have its own specific reference range.
- When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and red-top tubes. When coagulation testing is the only work to be

done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with tissue thromboplastin, which can falsely shorten PT.

- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed samples stored in unopened tubes is that testing should be completed within 1 to 4 hours of collection.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient to report bleeding from any areas of the skin or mucous membranes.
- Inform the patient with prolonged PT of the importance of taking precautions against bruising and bleeding, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of aspirin products, and avoidance of intramuscular injections.
- Inform the patient of the importance of periodic laboratory testing while taking an anticoagulant.
- *Nutritional considerations:* Foods high in vitamin K should be avoided by the patient on anticoagulant therapy. Foods that contain vitamin K include cabbage, cauliflower, chickpeas, egg yolks, green tea, liver, milk, soybean products, tomatoes, and green leafy vegetables such as brussels sprouts, kale, spinach, and turnip greens.
- *Nutritional considerations:* Avoid alcohol and alcohol products while taking warfarin, as the combination of the two increases the risk of gastrointestinal bleeding.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include alanine aminotransferase, aspartate aminotransferase, bilirubin, bleeding time, coagulation factors, complete blood count, γ-glutamyltranspeptidase, partial thromboplastin time, platelet count, and vitamin K.

PSEUDOCHOLINESTERASE AND DIBUCAINE NUMBER

SYNONYMS/ACRONYMS: CHS, PCHE, AcCHS.

SPECIMEN: Plasma (1 mL) collected in a lavender-top (ethylenediaminetetra-acetic acid [EDTA]) tube. Serum (1 mL) collected in a red-top tube is also acceptable.

REFERENCE VALUE: (Method: Spectrophotometry, kinetic)

Test	Conventional Units	SI Units (Conventional Units × 1)
Pseudocholinesterase	2–11 U/mL	2–11 kU/L

Dibucaine Number	Fraction (%) of Activity Inhibited	SI Units (Conventional Units × 0.01)
Normal homozygote	79–84%	0.79–0.84 kU/L
Heterozygote	55–70%	0.55–0.70 kU/L
Abnormal homozygote	16–28%	0.16–0.28 kU/L

DESCRIPTION & RATIONALE: There are two types of cholinesterase: *acetylcholinesterase,* which is found in red blood cells, lung, and brain (nerve) tissue (see monograph titled "Red Blood Cell Cholinesterase"); and *cholinesterase,* which is found mainly in the plasma, liver, and heart. Pseudocholinesterase is a nonspecific enzyme that hydrolyzes acetylcholine and noncholine esters; carbamate and organophosphate insecticides (e.g., parathion, malathion) inhibit its activity.

Patients with inherited pseudocholinesterase deficiency are at risk during anesthesia if succinylcholine is administered as an anesthetic. Succinylcholine, a short-acting muscle relaxant, is a reversible inhibitor of acetylcholinesterase and is hydrolyzed by cholinesterase. Succinylcholine-sensitive patients may be unable to metabolize the anesthetic quickly, resulting in prolonged or unrecoverable apnea. Abnormal genotypes of pseudocholinesterase are detected using the dibucaine and fluoride inhibition tests because, in normal individuals, these chemicals inhibit

pseudocholinesterase activity. The prevalence of succinylcholate sensitivity is 1 in 1500 patients. Widespread preoperative screening is not routinely performed. ■

INDICATIONS:

- Assist in the evaluation of liver function
- Screen for abnormal genotypes of pseudocholinesterase in patients with a family history of succinylcholine sensitivity who are about to undergo anesthesia using succinylcholine.

RESULT

Increased in:

- Diabetes
- Hyperthyroidism
- Nephrotic syndrome
- Obesity

Decreased in:

- Acute infection
- Anemia (severe)
- Carcinomatosis
- Cirrhosis
- Congenital deficiency
- Hepatic carcinoma
- Hepatocellular disease
- Infectious hepatitis
- Insecticide exposure (organic phosphate)
- Malnutrition
- Muscular dystrophy
- Myocardial infarction
- Plasmapheresis
- Succinylcholine hypersensitivity
- Tuberculosis
- Uremia

CRITICAL VALUES:

Notify the anesthesiologist if the test result is positive and surgery is scheduled. A positive result indicates that the patient is at risk for prolonged or unrecoverable apnea related to the inability to metabolize succinylcholine.

INTERFERING FACTORS:

- Drugs and substances that may decrease pseudocholinesterase levels include ambenonium, barbiturates, cyclophosphamide, echothiophate, edrophonium, estrogens, fluorides, ibuprofen, iodipamide, iopanoic acid, isoflurophate, neostigmine, parathion, physostigmine, procainamide, pyridostigmine, and oral contraceptives.
- Drugs that may increase pseudocholinesterase levels include carbamazepine, phenytoin, and valproic acid.
- Pregnancy decreases pseudocholinesterase levels by about 30%.
- Improper anticoagulant; fluoride interferes with the measurement and causes a falsely decreased value.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to identify succinylcholine anesthetic sensitivity.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly. Particularly important to report is exposure to pesticides causing symptoms including blurred vision, muscle weakness, nausea, vomiting, headaches, pulmonary edema, salivation, sweating, or convulsions.
- Obtain a history of the patient's hepatobiliary and musculoskeletal systems, as well as results of previ-

ously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hepatobiliary and Musculoskeletal System tables.

- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL lavender- or red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- The patient with decreased values should be observed for signs of fluid volume excess related to compromised regulatory mechanisms, decreased cardiac output related to decreased myocardial contractility or arrhythmias, and pain related to inflammation or ischemia.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include alanine aminotransferase and aspartate aminotransferase.

PULMONARY FUNCTION STUDIES

SYNONYM/ACRONYM: Pulmonary function tests (PFTs).

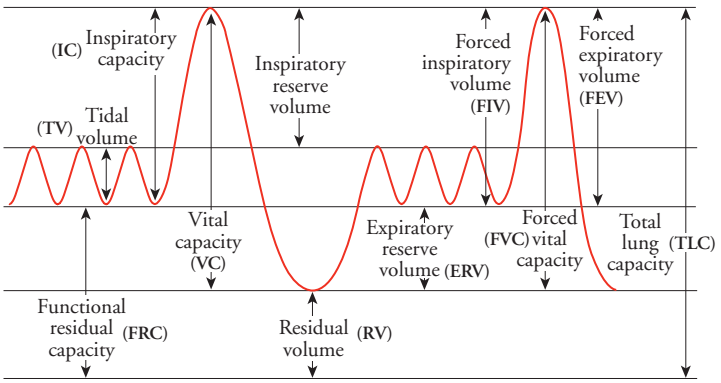
AREA OF APPLICATION: Lungs, respiratory system.

CONTRAST: None.

DESCRIPTION & RATIONALE: Pulmonary function studies provide information about the volume, pattern, and rates of airflow involved in respiratory function. These studies may also include tests involving the diffusing capabilities of the lungs (i.e., volume of gases diffusing across a membrane). A complete pulmonary study profile includes the determination of all lung volumes, spirometry, diffusing capacity, maximum voluntary ventilation, flow-volume loop (Fig. 1–1), and maximum expiratory and inspiratory pressures. Other studies include small airway volumes.

Pulmonary function studies are classified according to lung volumes and capacities, rates of flow, and gas exchange. The exception is the diffusion test, which records the movement of a gas during inspiration and expiration. Lung volumes and capacities constitute the amount of air inhaled or exhaled from the lungs; this value is compared to normal reference values specific for the patient's age, height, and sex. The following are volumes and capacities measured by spirometry that do not require timed testing. ■

TIDAL VOLUME: Total amount of air inhaled and exhaled with one breath.



RESIDUAL VOLUME: Amount of air remaining in the lungs after a maximum expiration effort (not measured by spirometry, but can be calculated from the functional residual capacity [FRC] minus the expiratory reserve volume [ERV]). This indirect type of measurement can be done by body plethysmography (see monograph titled "Plethysmography").

INSPIRATORY RESERVE VOLUME: Maximum amount of air inhaled after normal inspirations.

EXPIRATORY RESERVE VOLUME: Maximum amount of air exhaled after a resting expiration (can be calculated by the vital capacity [VC] minus the inspiratory capacity [IC]).

VITAL CAPACITY: Maximum amount of air exhaled after a maximum inspiration (can be calculated by adding the IC and the ERV).

TOTAL LUNG CAPACITY: Total amount of air that the lungs can hold after maximal inspiration (can be calculated by adding the VC and the residual volume [RV]).

INSPIRATORY CAPACITY: Maximum amount of air inspired after normal expiration (can be calculated by adding the inspiratory RV and tidal volume).

FUNCTIONAL RESIDUAL CAPACITY: Volume of air that remains in the lungs after normal expiration (can be calculated by adding the RV and ERV).

The volumes, capacities, and rates of flow measured by spirometry that do require timed testing include the following:

FORCED VITAL CAPACITY IN 1 SECOND: Maximum amount of air that can be forcefully exhaled after a full inspiration.

FORCED EXPIRATORY VOLUME: Amount of air exhaled in the first second (can also be determined at 2 or 3 seconds) of forced vital capacity (FVC, which is the amount of air exhaled in seconds, expressed as a percentage).

MAXIMAL MIDEXPIRATORY FLOW: Also known as forced expiratory flow rate ($FEF_{25–75}$), or the maximal rate of airflow during a forced expiration.

FORCED INSPIRATORY FLOW RATE: Volume inspired from the RV at a point of measurement (can be expressed as a percentage to identify the corresponding volume pressure and inspired volume).

PEAK INSPIRATORY FLOW RATE: Maximum airflow during a forced maximal inspiration.

PEAK EXPIRATORY FLOW RATE: Maximum airflow expired during FVC.

FLOW-VOLUME LOOPS: Flows and volumes recorded during forced expiratory volume and forced inspiratory vital capacity procedures (Fig. 1–2).

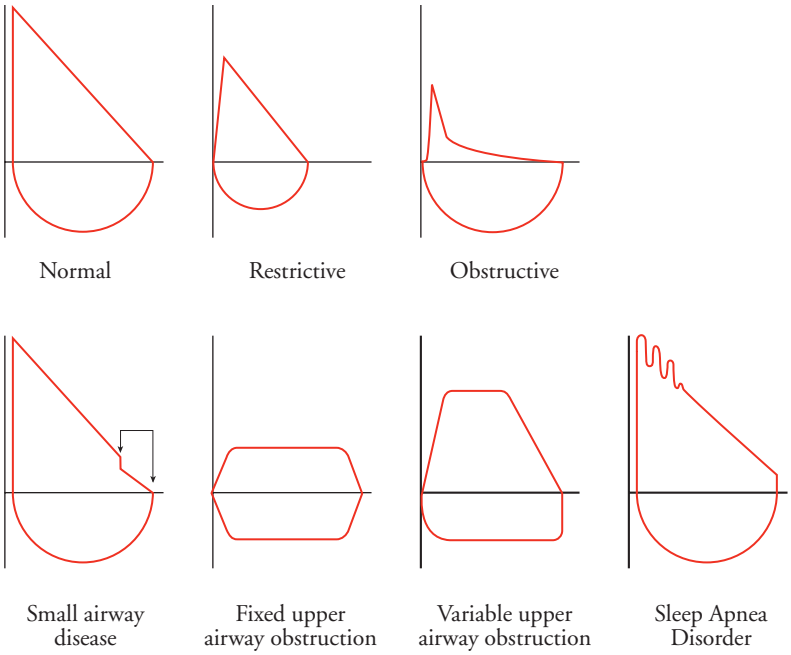
MAXIMAL INSPIRATORY-EXPIRATORY PRESSURES: Measures the strength of the respiratory muscles in neuromuscular disorders.

MAXIMAL VOLUNTARY VENTILATION: Maximal volume of air inspired and expired in 1 minute (may be done for shorter periods and multiplied to equal 1 minute).

Other studies for gas-exchange capacity, small airway abnormalities, and allergic responses in hyperactive airway disorders can be performed during the conventional pulmonary function study. These include the following:

DIFFUSING CAPACITY OF THE LUNGS: Rate of transfer of carbon monoxide through the alveolar and capillary membrane in 1 minute.

CLOSING VOLUME: Measures the closure



of small airways in the lower alveoli by monitoring volume and percentage of alveolar nitrogen after inhalation of 100% oxygen.

ISOFLOW VOLUME: Flow-volume loop test followed by inhalation of a mixture of helium and oxygen to determine small airway disease.

BODY PLETHYSMOGRAPHY: Measures thoracic gas volume and airway resistance.

BRONCHIAL PROVOCATION: Quantifies airway response after inhalation of methacholine.

ARTERIAL BLOOD GASES: Measure oxygen, pH, and carbon dioxide in arterial blood.

Values are expressed in units of mL, %, L, L/sec, and L/min, depending on the test performed.

INDICATIONS:

- Detect chronic obstructive pulmonary disease (COPD) and/or restrictive pulmonary diseases that affect the chest wall (e.g., neuromuscular disorders, kyphosis, scoliosis) and lungs, as evidenced by abnormal airflows and volumes
- Determine airway response to inhalants in patients with an airway-reactive disorder
- Determine the diffusing capacity of the lungs (DCOL)
- Determine the effectiveness of therapy regimens, such as bronchodilators, for pulmonary disorders
- Determine the presence of lung disease when other studies, such as x-rays, do not provide a definitive diagnosis, or determine the progression and severity of known COPD and restrictive pulmonary disease

- Evaluate the cause of dyspnea occurring with or without exercise
- Evaluate lung compliance to determine changes in elasticity, as evidenced by changes in lung volumes (decreased in restrictive pulmonary disease, increased in COPD and in elderly patients)
- Evaluate pulmonary disability for legal or insurance claims
- Evaluate pulmonary function after surgical pneumonectomy, lobectomy, or segmental lobectomy
- Evaluate the respiratory system to determine the patient's ability to tolerate procedures such as surgery or diagnostic studies
- Screen high-risk populations for early detection of pulmonary conditions (e.g., patients with exposure to occupational or environmental hazards, smokers, patients with a hereditary predisposition)

Result

Normal Findings:

- Normal respiratory volume and capacities, gas diffusion, and distribution
- No evidence of COPD or restrictive pulmonary disease

Normal adult lung volumes, capacities, and flow rates are as follows:

TV	500 mL at rest
RV	1200 mL (approximate)
IRV	3000 mL (approximate)
ERV	1100 mL (approximate)
VC	4600 mL (approximate)
TLC	5800 mL (approximate)
IC	3500 mL (approximate)
FRC	2300 mL (approximate)
FVC	3000–5000 mL (approximate)
FEV_1/FVC	81–83%
MMEF	25–75%
FIF	25–75%
MVV	25–35% or 170 L/min
PIFR	300 L/min
PEFR	450 L/min
F-V loop	Normal curve
DCOL	25 mL/min per mm Hg (approximate)
CV	10%–20% of VC
V_{iso}	Based on age formula
Bronchial provocation	No change, or less than 20% reduction in FEV_1

Note: Normal values listed are estimated values for adults. Actual pediatric and adult values are based on age, height, and gender. These normal values are included on the patient's pulmonary function laboratory report.
TV = tidal volume; RV = residual volume; IRV = inspiratory reserve volume; ERV = expiratory reserve volume; VC = vital capacity; TLC = total lung capacity; IC = inspiratory capacity; FRC = functional residual capacity; FVC = forced vital capacity in 1 second; FEV_1 = forced expiratory volume in 1 second; MMEF = maximal midexpiratory flow (also known as $FEF_{25–75}$); FIF = forced inspiratory flow rate; MVV = maximal voluntary ventilation; PIFR = peak inspiratory flow rate; PEFR = peak expiratory flow rate; F-V loop = flow-volume loop; DCOL = diffusing capacity of the lungs; CV = closing volume; V_{iso}= isoflow volume.

Abnormal Findings:

- Allergy
- Asbestosis
- Asthma
- Bronchiectasis
- Chest trauma
- Chronic bronchitis
- Curvature of the spine
- Emphysema
- Myasthenia gravis
- Obesity
- Pulmonary fibrosis
- Pulmonary tumors
- Respiratory infections
- Sarcoidosis

INTERFERING FACTORS:

- The aging process can cause decreased values (FVC, DCOL) depending on the study done.
- Inability of the patient to put forth the necessary breathing effort affects the results.
- Medications such as brochodilators can affect results.
- Improper placement of the nose clamp or mouthpiece that allows for leakage can affect volume results.
- Confusion or inability to understand instructions or cooperate during the study can cause inaccurate results.
- Testing is contraindicated in patients with cardiac insufficiency, recent myocardial infarction, and presence of chest pain that affects inspiration or expiration ability.
- Exercise caution with patients who have upper respiratory infections, such as a cold or acute bronchitis.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the function of the lungs.
- Obtain a history of the patient's complaints and symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient's cardiovascular and respiratory systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Cardiovascular and Respiratory Systems tables.
- Obtain a list of medications the patient is taking. Assess medication history for recent administration of analgesics that may depress respiratory function.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that no discomfort will be experienced during the test. Explain that the procedure is generally performed in a specially equipped room or in a health care practitioner's office by a technologist and usually lasts 1 hour.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Measure the patient's height and weight.
- The patient should refrain from smoking tobacco or eating a heavy meal for 4 to 6 hours prior to the study.
- Under medical direction, the patient should avoid bronchodilators (oral or inhalant) for at least 4 hours before the study.

Intratest:

- Ensure that the patient has complied with dietary restrictions and pretest-

ing preparations. Ensure that medications such as bronchodilators (oral or inhalant) have been withheld for at least 4 hours before the study.

- Obtain an inhalant bronchodilator to treat any bronchospasms that can occur with testing.
- Instruct the patient to void and to loosen any restrictive clothing.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in a sitting position on a chair near the spirometry equipment.
- Place a soft clip on the patient's nose to restrict nose breathing, and instruct the patient to breathe through the mouth.
- Place a mouthpiece in the mouth and tell the patient to close his or her lips around it to form a seal.
- Tubing from the mouthpiece is connected to a cylinder that is connected to a computer that measures, records, and calculates the values for the tests done.
- Instruct the patient to inhale deeply and then to quickly exhale as much air as possible into the mouthpiece.
- Additional breathing maneuvers are performed on inspiration and expiration (normal, forced, and breath-holding).
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Assess the patient for dizziness or weakness after the testing.
- Allow the patient to rest as long as needed to recover.
- Compare new pulmonary function test values with previous values to determine response to medical problem or treatment.
- Instruct the patient to resume usual diet and medications, as directed by the health care practitioner.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the thorax, chest x-ray, echocardiography, electrocardiogram, magnetic resonance imaging of the chest, and positron emission tomography of the chest.

PULSE OXIMETRY

SYNONYMS/ACRONYM: Oximetry, Pulse Ox.

AREA OF APPLICATION: Earlobe, fingertip; for infants, use the large toe, top or bottom of the foot, or sides of the ankle.

CONTRAST: None.

DESCRIPTION & RATIONALE: Pulse oximetry is a noninvasive study that provides continuous readings of arterial blood oxygen saturation (SPO_2) using a sensor site (earlobe or fingertip). The SPO_2 equals the ratio of the amount of O_2 contained in the hemoglobin to the maximum amount of O_2 contained with hemoglobin expressed as a percentage. The results obtained may compare favorably with O_2 saturation levels obtained by arterial blood gas (ABG) analysis without the need to perform successive arterial punctures. The device used is a clip or probe that produces a light beam with two different wavelengths on one side. A sensor on the opposite side measures the absorption of each of the wavelengths of light to determine the O_2 saturation reading. The displayed result is a ratio, expressed as a percentage, between the actual O_2 content of the hemoglobin and the potential maximum O_2-carrying capacity of the hemoglobin. ■

INDICATIONS:

- Determine the effectiveness of pulmonary gas exchange function
- Evaluate suspected nocturnal hypoxemia in chronic obstructive pulmonary disease (COPD)
- Monitor oxygenation during testing for sleep apnea
- Monitor oxygenation perioperatively and during acute illnesses
- Monitor oxygenation status in patients on a ventilator, during surgery, and during bronchoscopy
- Monitor O_2 saturation during activities such as pulmonary exercise stress testing or pulmonary rehabilitation exercises to determine optimal tolerance
- Monitor response to pulmonary drug regimens, especially flow and O_2 content

RESULT

Normal Findings:

- Greater than or equal to 95%

Abnormal Findings:

- Abnormal gas exchange
- Hypoxemia with levels less than 95%
- Impaired cardiopulmonary function

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who smoke or have suffered carbon monoxide inhalation, because O_2 levels may be falsely elevated

Factors that may result in incorrect values:

- Patients with anemic conditions reflecting a reduction in hemoglobin, the O_2-carrying component in the blood
- Excessive light surrounding the patient, such as from surgical lights
- Impaired cardiopulmonary function
- Lipid emulsion therapy and presence of certain dyes
- Movement of the finger or ear or improper placement of probe or clip
- Nail polish, false fingernails, and skin pigmentation when a finger probe is used
- Vasoconstriction from cool skin temperature, drugs, hypotension, or vessel obstruction causing a decrease in blood flow

Other considerations:

- Accuracy for most units is plus or minus 4% with a standard deviation of 1%.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure is used to monitor oxygenation of the blood.
- Obtain a history of the patient's respiratory and cardiovascular systems, reason for monitoring procedure, and results of previously performed laboratory tests (especially ABG results), surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Respiratory and Cardiovascular System tables.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that no pain is associated with the procedure. Inform the patient that the procedure is generally performed at the bedside, in the operating room during a surgical procedure, or in a health care practitioner's office. Explain that the procedure lasts as long as the monitoring is needed and could be continuous.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient not to smoke for 24 hours before the procedure.
- If a finger probe is used, instruct the patient to remove false fingernails and nail polish.
- If a finger probe is used, instruct the patient not to grip treadmill rail or bedrail tightly; doing so restricts blood flow.
- When used in the presence of flammable gases, the equipment must be approved for that specific use.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient does not have false fingernails and that nail polish has been removed.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Massage or apply a warm towel to the upper earlobe or finger to increase the blood flow.
- The index finger is normally used, but if the patient's finger is too large for the probe, a smaller finger can be used.

- If the earlobe is used, make sure good contact is achieved.
- With infants, the big toe, top or bottom of the foot, or sides of the heel may be used.
- Place the photodetector probe over the finger in such a way that the light beams and sensors are opposite each other. Turn the power switch to the oximeter monitor, which will display information about heart rate and SaO_2.
- Remove the clip used for monitoring when the procedure is complete.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Compare new value with previous value to determine response to medical problem or treatment.
- Consider results as they relate to ABGs.
- Closely observe SPO_2, and report to the health care practitioner if it decreases to 90%.
- Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography angiography, chest x-ray, electrocardiogram, magnetic resonance angiography, magnetic resonance imaging of the chest, and pulmonary function tests.

PYRUVATE KINASE

SYNONYM/ACRONYM: PK.

SPECIMEN: Whole blood collected in yellow-top (acid-citrate-dextrose [ACD]) tube. Specimens collected in a lavender-top (ethylenediaminetetraacetic acid [EDTA]) or green-top (heparin) tube also may be acceptable in some laboratories.

REFERENCE VALUE: (Method: Spectrophotometry) 9 to 22 U/g hemoglobin.

DESCRIPTION & RATIONALE: Pyruvate kinase is an enzyme that forms pyruvate and adenosine diphosphate (ADP) during glycolysis. Deficiency of this enzyme can be acquired by ingestion of a drug or as an effect of liver disease. There is also a hereditary form of pyruvate kinase deficiency

that can be transmitted as an autosomal recessive trait. Red blood cells lacking this enzyme have a membrane defect resulting from low levels of adenosine triphosphate (ATP) and are more susceptible to hemolysis. ■

INDICATIONS: Evaluate chronic hemolytic anemia

RESULT

Increased in:

- Carriers of Duchenne's muscular dystrophy
- Muscle disease
- Myocardial infarction

Decreased in:

- Hereditary pyruvate kinase deficiency:
  Congenital nonspherocytic hemolytic anemia
- Acquired pyruvate kinase deficiency:
  Acute leukemia
  Aplasias
  Other anemias

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Testing after blood transfusion may produce a falsely normal result.
- The enzyme is unstable. The specimen should be refrigerated immediately after collection.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to identify pyruvate kinase enzyme deficiency.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic system as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic System table.
- Note any recent procedures that can interfere with test results.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient is regularly using these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL yellow-top tube.
- Remove the needle, and apply a

pressure dressing over the puncture site.

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include complete blood count, glucose-6-phosphate dehydrogenase, Ham's test, and osmotic fragility test.

RADIOACTIVE IODINE UPTAKE

SYNONYM/ACRONYM: Thyroid uptake, RAIU.

AREA OF APPLICATION: Thyroid.

CONTRAST: Oral radioactive iodine.

DESCRIPTION & RATIONALE: Radioactive iodine uptake (RAIU) is a nuclear medicine study used for evaluating thyroid function. It directly measures the ability of the thyroid gland to concentrate and retain circulating iodide for the synthesis of thyroid hormone. RAIU assists in the diagnosis of both hyperthyroidism and hypothyroidism, but it is more useful in the diagnosis of hyperthyroidism.

A very small dose of radioactive iodine-123 (I-123) or I-131 is administered orally and images are taken at specified intervals after the initial dose is administered. The radionuclide emits gamma radiation, which allows

external measurement. The uptake of radionuclide in the thyroid gland is measured as the percentage of radionuclide absorbed in a specific amount of time. The iodide not used is excreted in the urine. The thyroid gland does not distinguish between radioactive and nonradioactive iodine. Uptake values are used in conjunction with measurements of circulating thyroid hormone levels to differentiate primary and secondary thyroid disease, and serial measurements are helpful in long-term management of thyroid disease and its treatment. ■

INDICATIONS:

- Evaluate hyperthyroidism and/or hypothyroidism
- Evaluate neck pain
- Evaluate the patient as part of a complete thyroid evaluation for symptomatic patients (e.g., swollen neck, neck pain, extreme sensitivity to heat or cold, jitters, sluggishness)
- Evaluate thyroiditis, goiter, or pituitary failure
- Monitor response to therapy for thyroid disease

RESULT

Normal Findings:

- Variations in normal ranges of iodine uptake can occur with differences in dietary intake, geographic location, and protocols among laboratories:

Iodine Uptake	Percentage of Radionuclide
2-h absorption	1%–13%
6-h absorption	2%–25%
24-h absorption	15%–45%

Abnormal Findings:

- Decreased iodine intake or increased iodine excretion
- Graves' disease
- Iodine-deficient goiter
- Hashimoto's thyroiditis (early)
- Hyperthyroidism, increased uptake of:

Iodine Uptake	Percentage of Radionuclide
1-h absorption	20%
6-h absorption	25%
24-h absorption	45%

  Rebound thyroid hormone withdrawal

  Drugs and hormones such as barbiturates, diuretics, estrogens, lithium carbonate, phenothiazines, and thyroid-stimulating hormone

- Decreased uptake:

  Hypothyroidism, with a response of decreased uptake of 0 to 10% over a 24-hour period

- Hypoalbuminemia
- Malabsorption
- Renal failure
- Subacute thyroiditis
- Thyrotoxicosis as a result of ectopic thyroid metastasis

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure be-

cause of age, significant pain, or mental status

- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Recent use of iodinated contrast medium for radiographic studies (within the last 4 weeks) or nuclear medicine procedures done within the previous 24 to 48 hours
- Iodine deficiency (e.g., patients with inadequate dietary intake, patients on phenothiazine therapy), which can increase radionuclide uptake
- Certain drugs and other external sources of excess iodine, which can decrease radionuclide uptake, as follows:

  Foods containing iodine (e.g., iodized salt)

  Drugs such as aminosalicylic acid, antihistamines, antithyroid medications (e.g., propylthiouracil, iodothiouracil), corticosteroids, cough syrup, isoniazid, levothyroxine sodium/T_4, L-triiodothyronine, Lugol's solution, nitrates, penicillins, potassium iodide, propylthiouracil, saturated solution of potassium iodide (SSKI), sulfonamides, thiocyanate, thyroid extract, tolbutamide, and warfarin

  Multivitamins containing minerals
- Vomiting, severe diarrhea, and gastroenteritis, which can affect absorption of the oral radionuclide dose
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images

Other considerations:

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Consultation with a health care professional should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses thyroid function.
- Obtain a history of the patient's complaints and symptoms, including a list of known allergens.
- Obtain a history of the patient's endocrine system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Endocrine System table.
- Ensure that this procedure is performed before all radiographic procedures using iodinated contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient's current medications.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Explain the purpose of the test and how the procedure is performed. Inform the patient that the procedure is performed in a nuclear medicine department, usually by a technologist and support staff, and takes approximately 15 to 30 minutes, and

that delayed images or data collection is needed 24 hours later. The patient may leave the department and return later to undergo delayed data collection.

- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.
- The patient should fast for 8 to 12 hours before the procedure, but the patient may eat 4 hours after the test begins, unless otherwise indicated.

Intratest:

- Ensure that the patient has fasted for 8 to 12 hours before the uptake, but the patient may eat 4 hours after the test begins, unless otherwise indicated. Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) from the neck area prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer the I-123 orally (pill form).
- At 2, 6, and 24 hours, place the patient in a sitting or supine position in front of a radionuclide detector that will determine the thyroid gland's ability to bind iodine.
- Wear gloves during the radionuclide administration and while handling the patient's urine.
- The results are recorded on film or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, as directed by the health care practitioner.
- Advise patient to drink increased amounts of fluids for 24 hours to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 24 to 48 hours.
- If a woman who is breast-feeding must have a nuclear scan, she should not breast-feed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- Instruct the patient to flush the toilet immediately after each voiding following the procedure, and to wash hands meticulously with soap and water after each voiding for 24 hours after the procedure.
- Tell all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the spine, upper gastrointestinal series, and ultrasound of the thyroid.

RADIOFREQUENCY ABLATION, LIVER

SYNONYMS/ACRONYM: RFA, RF ablation.

AREA OF APPLICATION: Liver.

CONTRAST: Intravenous iodine based.

DESCRIPTION & RATIONALE: One minimally invasive therapy to eliminate tumors in organs such as the liver is called radiofrequency ablation (RFA). This technique works by passing electrical current in the range of radiofrequency waves between the needle electrode and the grounding pads placed on the patient's skin. A special needle electrode is placed in the tumor under the guidance of an imaging method such as ultrasound, computed tomography (CT) scanning, or magnetic resonance imaging (MRI). A radiofrequency current is then passed through the electrode to heat the tumor tissue near the needle tip and to ablate, or eliminate, it. The current creates heat around the electrode inside the tumor, and this heat spreads out to destroy the entire tumor, but little of the surrounding normal liver tissue. The heat from radiofrequency energy also closes up small blood vessels, thereby minimizing the risk of bleeding. Because healthy liver tissue withstands more heat than a tumor, RFA is able to destroy a tumor and a small rim of normal tissue about its edges without affecting most of the normal liver. The dead tumor cells are gradually replaced by scar tissue that shrinks over time. Some liver tumors may have failed to respond to chemotherapy, or have recurred after initial surgery, and may be treated by RFA. If there are multiple tumor nodules, they may be treated in one or more sessions. In general, RFA causes only minimal discomfort and may be done as an outpatient procedure without general anesthesia. RFA is most effective if the tumor or tumors are less than 2 inches in diameter; results are not as good when RFA is used to treat larger tumors. Similar therapy is being used to treat tumors in the kidney, pancreas, bone, thyroid, breast, adrenal gland, and lung. ■

INDICATIONS:

- Ablation of metastases to the liver
- Ablation of primary liver tumors, with hepatocellular carcinoma
- Therapy for multiple small liver tumors that are too spread out to remove surgically
- Therapy for recurrent liver tumors
- Therapy for tumors that are less than 2 inches in diameter
- Therapy for tumors that have failed to respond to chemotherapy
- Therapy for tumors that have recurred after initial surgery

RISKS:

- May cause brief or long-lasting shoulder pain.
- May cause inflammation of the gallbladder.
- May cause damage to the bile ducts with resulting biliary obstruction.
- May cause thermal damage to the bowel.
- The patient may experience flu-like symptoms that appear 3 to 5 days after the procedure and last for approximately 5 days.
- The patient may experience bleeding. If bleeding is severe, surgery may be needed.

INTERFERING FACTORS

This procedure is contraindicated for:

- Patients with bleeding disorders
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Metallic objects within the examination field (e.g., jewelry, rings, surgery clips), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:

- Failure to follow dietary restrictions and other pretesting preparations before the procedure may cause the procedure to be canceled or repeated.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses liver function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, and dyes), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hepatobiliary system, blood tests, and results of previously performed laboratory tests (especially coagulation tests), surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Hepatobiliary System table.
- Note any recent procedures that can interfere with test results, including barium examinations.
- Record the date of the last menstrual

period and determine the possibility of pregnancy in perimenopausal women.

- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the needle electrode insertion. Explain to the patient that any discomfort with the needle electrode will be minimized with local anesthetics and systemic analgesics. Inform the patient that the procedure is performed in the radiology department by a physician and support staff, and takes approximately 30 to 90 minutes.
- Explain that an intravenous (IV) line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- The patient should fast and restrict fluids for 8 hours prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects from the area to be examined.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*
- This procedure may be terminated if chest pain or severe cardiac arrhythmias occur.

Intratest:

- Ensure that the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations; assure that these have been restricted for at least 8 hours prior to the procedure. Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs and assess neurologic status. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.

- Using a pen, mark the site of the patient's peripheral pulses before the procedure begins; this allows for quicker and more consistent assessment of the pulses after the procedure.
- Place the patient in the supine position on an exam table. Cleanse the selected area, and cover with a sterile drape.
- A local anesthetic is injected at the site, and a needle electrode is inserted under ultrasound, CT, or MRI guidance.
- A radiofrequency current is passed through the needle electrode, and the tumor is ablated.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- The needle electrode is removed, and a pressure dressing is applied over the puncture site.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The results are recorded manually, on x-ray film, or electronically in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the health care practitioner.
- Monitor vital signs and neurologic status every 15 minutes for 1 hour, then every 2 hours for 4 hours, and as ordered. Take temperature every 6 hours for 24 hours. Compare with baseline values. Notify the health care practitioner if temperature is elevated. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching or decreased urinary output.
- Observe the needle electrode insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- Instruct the patient to maintain bed rest for 4 to 6 hours after the procedure or as ordered.
- Instruct the patient in the care and assessment of the site. Observe for bleeding, hematoma formation, bile leakage, and inflammation. Note any pleuritic pain, persistent right shoulder pain, or abdominal pain.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to physical activity. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include angiography of the abdomen, computed tomography of the liver, magnetic resonance imaging of the abdomen, and ultrasound of the liver and biliary system.

RADIOGRAPHY, BONE

SYNONYM/ACRONYM: Bone x-rays, hand x-rays, foot x-rays, wrist x-rays, arm x-rays.

AREA OF APPLICATION: Skeleton.

CONTRAST: None.

DESCRIPTION & RATIONALE: Skeletal x-rays are used to evaluate extremity pain or discomfort due to trauma, bone abnormalities, or fluid within a joint. Serial skeletal x-rays are used to evaluate growth pattern. Radiation emitted from the x-ray machine passes through the patient onto a photographic plate or x-ray film. X-rays pass through air freely and are mostly absorbed by the photographic media. Bones and tissues absorb the x-rays in varying degrees, thereby causing white and shades of gray on the x-ray recording media: Bones are very dense and therefore absorb most of the x-ray and appear white; organs are denser than air but not as dense as bone, so they appear in shades of gray. All metals absorb x-rays. Because the x-ray is absorbed or blocked, metal appears totally white on the film and thus facilitates the search for foreign bodies in the patient. ■

INDICATIONS:

- Assist in detecting bone fracture, dislocation, deformity, and degeneration
- Evaluate for child abuse
- Evaluate growth pattern
- Identify abnormalities of bones, joints, and surrounding tissues
- Monitor fracture healing process

RESULT

Normal Findings:

- *Infants and children:* Thin plate of cartilage, known as growth plate or epiphyseal plate, between the shaft and both ends

- *Adolescents and adults:* By age 17, calcification of cartilage plate; no evidence of fracture, congenital abnormalities, tumors, or infection

Abnormal Findings:

- Arthritis
- Bone degeneration
- Bone spurs
- Foreign bodies
- Fracture
- Genetic disturbance (achondroplasia, dysplasia, dyostosis)
- Hormonal disturbance
- Infection, including osteomyelitis
- Injury
- Joint dislocation or effusion
- Nutritional or metabolic disturbances
- Osteoporosis or osteopenia
- Soft-tissue abnormalities
- Tumor or neoplastic disease (osteogenic sarcoma, Paget's disease, myeloma)

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings, dental amalgams), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:

- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses bone structure of the area examined.
- Obtain a history of the patient's complaints.
- Obtain a history of results of previously performed diagnostic procedures, surgical procedures, and laboratory tests. For related diagnostic tests, refer to the Musculoskeletal System.
- Note any recent procedures that can interfere with test results.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.

- Review the procedure with the patient. Explain that numerous x-rays may be taken depending on the bones or joint affected. Explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Inform the patient that the procedure is performed in the radiology department by a radiologic technologist and support staff, and takes approximately 10 to 30 minutes.
- Instruct the patient to inhale deeply and hold his or her breath while the x-ray is taken and then to exhale after the film is taken. Warn the patient that the extremity's position during the procedure may be uncomfortable, but ask the patient to hold very still during the procedure because movement will produce unclear images.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.

Intratest:

- Ensure that the patient has removed all external metallic objects (wires, jewelry, etc.) prior to the procedure.
- Have emergency equipment readily available.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place patient in a standing, sitting, or recumbent position in front of the x-ray film holder or electronic receiver.
- Ask the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- The results are recorded on x-ray film or electronically, in a computerized system, for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to the perceived loss of daily function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Explain the importance of adhering to the therapy regimen. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include bone scan, computed tomography of the spine, and musculoskeletal magnetic resonance imaging.

RED BLOOD CELL CHOLINESTERASE

SYNONYMS/ACRONYMS: acetylcholinesterase (AChE), erythrocyte cholinesterase, true cholinesterase.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

REFERENCE VALUE: (Method: Spectrophotometry, kinetic)

Test	Conventional Units	SI Units (Conventional Units × 1)
RBC cholinesterase	5–10 U/mL	5–10 kU/L

DESCRIPTION & RATIONALE: There are two types of cholinesterase enzyme: *acetylcholinesterase (AChE),* which is found in red blood cells (RBCs), lung, and brain (nerve) tissue; and *cholinesterase,* which is mainly found in the plasma, liver, and heart. RBC AChE is highly specific for acetylcholine. Cholinesterase has broader esterolytic activity and is referred to as "pseudocholinesterase." Pseudocholinesterase is the test used to indicate succinylcholine sensitivity (see monograph titled "Pseudocholinesterase and Dibucaine Number"). RBC cholinesterase is used to assist in the diagnosis of chronic carbamate or organophosphate insecticide (e.g., parathion, malathion) toxicity. Organophosphate pesticides bind irreversibly with cholinesterase, inhibiting normal enzyme activity. Carbamate insecticides bind reversibly. Serum or plasma pseudocholinesterase is used more frequently to measure acute pesticide toxicity.

Patients with inherited cholinesterase deficiency are at risk during anesthesia if succinylcholine is administered as an anesthetic. Succinylcholine, a short-acting muscle relaxant, is a reversible inhibitor of acetylcholinesterase and is hydrolyzed by cholinesterase. Succinylcholine-sensitive patients may be unable to metabolize the anesthetic quickly, resulting in prolonged or unrecoverable apnea. This test, along with the pseudocholinesterase test, is also used to identify individuals with atypical forms of the enzyme cholinesterase (see monograph titled "Pseudocholinesterase and Dibucaine Number"). The prevalence of succinylcholate sensitivity is 1 in 1500 patients. Widespread preoperative screening is not routinely performed. ■

INDICATIONS:

- Monitor cumulative exposure to organic phosphate insecticides
- Verify suspected exposure to organic phosphate insecticides

RESULT

Increased in:

- Sickle cell anemia

Decreased in:

- Insecticide exposure (organic phosphate)
- Late pregnancy
- Paroxysmal nocturnal hemoglobinuria
- Relapse of megaloblastic anemia

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs and substances that may increase RBC cholinesterase levels include echothiophate, parathion, and antiepileptic drugs such as carbamazepine, phenobarbital, phenytoin, and valproic acid.
- Improper anticoagulant; fluoride interferes with the measurement and causes a falsely decreased value.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to identify pesticide poisoning.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly. Particularly important to report is exposure to pesticides causing symptoms including blurred vision, muscle weakness, nausea, vomiting, headaches, pulmonary edema, salivation, sweating, or convulsions.
- Obtain a history of exposure to occupational hazards and medication regimen.
- Obtain a history of the patient's hematopoietic system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic System table.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL lavender-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.

- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include complete blood count and pseudocholinesterase.

RED BLOOD CELL COUNT

SYNONYM/ACRONYM: RBC.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

REFERENCE VALUE: (Method: Automated, computerized, multichannel analyzers that sort and size cells on the basis of changes in either electrical impedance or light pulses as the cells pass in front of a laser)

Age	Conventional Units	SI Units (Conventional Units × 1)
Cord Blood	4.14–4.69 × 10^6 cells/mm^3	4.14–4.69 × 10^{12} cells/L
1 d	5.33–5.47 × 10^6 cells/mm^3	5.33–5.47 × 10^{12} cells/L
2 wk	4.32–4.98 × 10^6 cells/mm^3	4.32–4.98 × 10^{12} cells/L
1 mo	3.75–4.95 × 10^6 cells/mm^3	3.75–4.95 × 10^{12} cells/L
6 mo	3.71–4.25 × 10^6 cells/mm^3	3.71–4.25 × 10^{12} cells/L
1 y	4.40–4.48 × 10^6 cells/mm^3	4.40–4.48 × 10^{12} cells/L
10 y	4.75–4.85 × 10^6 cells/mm^3	4.75–4.85 × 10^{12} cells/L
Adult male	4.71–5.14 × 10^6 cells/mm^3	4.71–5.14 × 10^{12} cells/L
Adult female	4.20–4.87 × 10^6 cells/mm^3	4.20–4.87 × 10^{12} cells/L

DESCRIPTION & RATIONALE: A component of the complete blood count (CBC), the red blood cell (RBC) count determines the number of RBCs per cubic millimeters (expressed as the number of RBCs per liter of blood according to the international system of units [SI]). Because RBCs contain hemoglobin (Hgb), which is responsible for the transport and exchange of oxygen, the number of circulating RBCs is important. Although the life span of the normal RBC is 120 days, other factors besides cell age and decreased production can cause decreased values; examples are abnormal destruction due to intravascular trauma caused by atherosclerosis or to an enlarged spleen caused by leukemia. The main sites of RBC production in healthy adults include the bone marrow of the vertebrae, pelvis, ribs, sternum, skull, and proximal ends of the femur and humerus. The main sites of RBC destruction are the spleen and liver. Erythropoietin, a hormone produced by the kidneys, regulates RBC production. Normal RBC development and function are also dependent on adequate levels of vitamin B_{12}, folic acid, and iron. A deficiency in vitamin E (α-tocopherol), which is needed to protect the RBC membrane from oxidizers, can result in increased cellular destruction. *Polycythemia* is a term used in conjunction with conditions resulting from an abnormal increase in Hgb, hematocrit (Hct), and RBC count. *Anemia* is a term associated with conditions resulting from an abnormal decrease in Hgb, Hct, and RBC count. Results of the Hgb, Hct, and RBC count should be evaluated simultaneously because the same underlying conditions affect this triad of tests similarly. The RBC count multiplied by 3 should approximate the Hgb concentration. The Hct should be within three times the Hgb if the RBC population is normal in size and shape. The Hct plus 6 should approximate the first two figures of the RBC count within 3 (e.g., Hct is 40%; therefore 40 + 6 = 46, and the RBC count should be 4.3 to 4.9). (See monographs titled "Hematocrit," "Hemoglobin," and "Red Blood Cell Indices.") ■

INDICATIONS:

- Detect a hematologic disorder involving RBC destruction (e.g., hemolytic anemia)
- Determine the presence of hereditary hematologic abnormality
- Monitor the effects of acute or chronic blood loss
- Monitor the effects of physical or emotional stress on the patient
- Monitor patients with disorders associated with elevated erythrocyte counts (e.g., polycythemia vera, chronic obstructive pulmonary disease [COPD])
- Monitor the progression of nonhematologic disorders associated with elevated erythrocyte counts, such as COPD, liver disease, hypothyroidism, adrenal dysfunction, bone marrow failure, malabsorption syndromes, cancer, and renal disease
- Monitor the response to drugs or chemotherapy and evaluate undesired reactions to drugs that may cause blood dyscrasias
- Provide screening as part of a CBC in a general physical examination, especially upon admission to a health care facility or before surgery

Result

Increased in:

- Anxiety or stress
- Bone marrow failure
- COPD with hypoxia and secondary polycythemia
- Dehydration with hemoconcentration
- Erythremic erythrocytosis
- High altitude
- Polycythemia vera

Decreased in:

- Chemotherapy
- Chronic inflammatory diseases
- Hemoglobinopathy
- Hemolytic anemia
- Hemorrhage
- Hodgkin's disease
- Leukemia
- Multiple myeloma
- Nutritional deficit
- Organ failure
- Overhydration
- Pregnancy (normal dilutional effect)
- Subacute endocarditis

Critical Values:

The presence of abnormal cells, other morphologic characteristics, or cellular inclusions may signify a potentially life-threatening or serious health condition and should be investigated. Examples are the presence of sickle cells, moderate numbers of spherocytes, marked schistocytosis, oval macrocytes, basophilic stippling, nucleated RBCs (if the patient is not an infant), or malarial organisms.

Note and immediately report to the health care practitioner any critically increased or decreased values and related symptoms.

- Low RBC count leads to anemia. Anemia can be caused by blood loss, decreased blood cell production, increased blood cell destruction, or hemodilution. Causes of blood loss include menstrual excess or frequency, gastrointestinal bleeding, inflammatory bowel disease, or hematuria. Decreased blood cell production can be caused by folic acid deficiency, vitamin B_{12} deficiency, iron deficiency, or chronic disease. Increased blood cell destruction can be caused by a hemolytic reaction, chemical reaction, medication reaction, or sickle cell disease. Hemodilution can be caused by congestive heart failure, renal failure, polydipsia, or overhydration. Symptoms of anemia (due to these causes) include anxiety, dyspnea, edema, hypertension, hypotension, hypoxia, jugular venous distention, fatigue, pallor, rales, restlessness, and weakness. Treatment of anemia depends on the cause.
- High RBC count leads to polycythemia. Polycythemia can be caused by dehydration, decreased oxygen levels in the body, and an overproduction of RBCs by the bone marrow. Dehydration by diuretic use, vomiting, diarrhea, excessive sweating, severe burns, or decreased fluid intake decreases the plasma component of whole blood, thereby increasing the ratio of RBCs to plasma, and leads to a higher than normal Hct. Causes of decreased oxygen include smoking, exposure to carbon monoxide, high altitude, and chronic lung disease, which leads to a mild hemoconcentration of blood in the body to carry more oxygen to the body's tissues. An overproduction of RBCs by the bone marrow leads to polycythemia vera, which is a rare chronic myeloproliferative disorder that leads to a severe hemoconcentration of blood. Severe hemoconcentration can lead to thrombosis (spontaneous blood clotting). Symptoms of hemoconcentration include decreased pulse pressure and volume,

loss of skin turgor, dry mucous membranes, headaches, hepatomegaly, low central venous pressure, orthostatic hypotension, pruritis (especially after a hot bath), splenomegaly, tachycardia, thirst, tinnitus, vertigo, and weakness. Treatment of polycythemia depends on the cause. Possible interventions for hemoconcentration due to dehydration include intravenous fluids and discontinuance of diuretics if they are believed to be contributing to critically elevated Hct. Polycythemia due to decreased oxygen states can be treated by removal of the offending substance, such as smoke or carbon monoxide. Treatment includes oxygen therapy in cases of smoke inhalation, carbon monoxide poisioning, and desaturating chronic lung disease. Symptoms of polycythemic overload crisis include signs of thrombosis, pain and redness in extremities, facial flushing, and irritability. Possible interventions for hemoconcentration due to polycythemia include therapeutic phlebotomy and intravenous fluids.

INTERFERING FACTORS:

- Drugs and substances that may decrease RBC count by causing hemolysis resulting from drug sensitivity or enzyme deficiency include such as acetaminophen, aminopyrine, aminosalicylic acid, amphetamine, anticonvulsants, antipyrine, arsenicals, benzene, busulfan, carbenicillin, cephalothin, chemotherapy drugs, chlorate, chloroquine, chlorothiazide, chlorpromazine, colchicine, diphenhydramine, dipyrone, glucosulfone, gold, hydroflumethiazide, indomethacin, mephenytoin, nalidixic acid, neomycin, nitrofurantoin, penicillin, phenacemide, phenazopyridine, and phenothiazine.
- Drugs that may decrease RBC count by causing anemia include miconazole, penicillamine, phenylhydrazine, primaquine, probenecid, pyrazolones, pyrimethamine, quinines, streptomycin, sulfamethizole, sulfamethoxypyridine, sulfisoxazole, suramin, thioridazine, tolbutamide, trimethadione, and tripelennamine.
- Drugs that may decrease RBC count by causing bone marrow suppression include amphotericin B, floxuridine, and phenylbutazone.
- Drugs and vitamins that may increase the RBC count include glucocorticosteroids, pilocarpine, and vitamin B_{12}.
- Use of the neutraceutical liver extract is strongly contraindicated in patients with iron-storage disorders such as hemochromatosis because it is rich in heme (the iron-containing pigment in Hgb).
- Hemodilution (e.g., excessive administration of intravenous fluids, normal pregnancy) in the presence of a normal number of RBCs may lead to false decreases in RBC count.
- Cold agglutinins may falsely increase the mean corpuscular volume (MCV) and decrease the RBC count. This can be corrected by warming the blood or diluting the sample with warmed saline and repeating the analysis.
- Excessive exercise, anxiety, pain, and dehydration may cause false elevations in RBC count.
- A grossly elevated white blood cell (WBC) count (greater than $500 \times 10^3/mm^3$) will cause a falsely elevated RBC count. This can be corrected by diluting the sample with saline to obtain an accurate WBC count and then correcting the RBC mathematically.
- Care in evaluating the CBC after transfusion should be taken into consideration.
- RBC counts can vary depending on the patient's position, decreasing when the patient is recumbent as a result of hemodilution and increasing when the patient rises as a result of hemoconcentration.

- Venous stasis can falsely elevate RBC counts; therefore, the tourniquet should not be left on the arm for longer than 60 seconds.
- Failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.
- Hemolyzed or clotted specimens must be rejected for analysis.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate anemia and disorders affecting the number of circulating red blood cells.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular, gastrointestinal, hematopoietic, hepatobiliary, immune, musculoskeletal, and respiratory systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Cardiovascular, Gastrointestinal, Hematopoietic, Hepatobiliary, Immune, Musculoskeletal, and Respiratory System tables.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL lavender-top (EDTA) tube. An EDTA Microtainer sample may be obtained from infants, children, and adults for whom venipuncture may not be feasible. The specimen should be mixed gently by inverting the tube 10 times. The specimen should be analyzed within 6 hours when stored at room temperature or within 24 hours if stored at refrigerated temperature. If it is anticipated the specimen will not be analyzed within 4 to 6 hours, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 6 hours will contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and

spherocytes, as well as necrobiotic WBCs.

- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Nutritional therapy may be indicated for patients with decreased RBC count. Iron deficiency is the most common nutrient deficiency in the United States. Patients at risk (e.g., children, pregnant women and women of childbearing age, low-income populations) should be instructed to include foods that are high in iron in their diet, such as meats (especially liver), eggs, grains, green leafy vegetables, and multivitamins with iron. Iron absorption is affected by numerous factors (see monograph titled "Iron").
- *Nutritional considerations:* Patients at risk for vitamin B_{12} or folate deficiency include those with the following conditions: malnourishment (inadequate intake), pregnancy (increased need), infancy, malabsorption syndromes (inadequate absorption/increased metabolic rate), infections, cancer, hyperthyroidism, serious burns, excessive blood loss, and gastrointestinal damage. These patients should be instructed, as appropriate, to ingest food sources rich in vitamin B_{12}, such as meats, milk, cheese, eggs, and fortified soy milk products. Sources of folate are meats (especially liver), kidney beans, beets, vegetables in the cabbage family, oranges, cantaloupe, and green leafy vegetables such as spinach, asparagus, and broccoli.
- *Nutritional considerations:* A diet deficient in vitamin E puts the patient at risk for increased RBC destruction, which could lead to anemia. Nutritional therapy may be indicated for these patients. Vitamin E is found in many of the previously mentioned foods, as well as in vegetable oils and wheat germ. Supplemental vitamin E may also be taken, but the danger of toxicity should be explained to the patient. Very large supplemental doses, in excess of 600 mg of vitamin E over a period of 1 year, may result in excess bleeding. Vitamin E is heat stable but is very negatively affected by light.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include the other tests included in a CBC, erythropoietin, ferritin, folate, iron/total iron-binding capacity, RBC morphology and inclusions, reticulocyte count, and vitamin B_{12}.

RED BLOOD CELL INDICES

SYNONYMS/ACRONYMS: mean corpuscular hemoglobin (MCH), mean corpuscular volume (MCV), mean corpuscular hemoglobin concentration (MCHC), red blood cell distribution width (RDW).

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

REFERENCE VALUE: (Method: Automated, computerized, multichannel analyzers that sort and size cells on the basis of changes in either electrical impedance or light pulses as the cells pass in front of a laser)

Age	MCV (fL)	MCH (pg/cell)	MCHC (g/dL)	RDW
Cord blood	107–119	35–39	32–34	14.9–18.7
1 d	104–116	35–39	32–34	14.9–18.7
2 wk	95–117	29–35	28–32	14.9–18.7
1 mo	93–115	29–35	28–34	14.9–18.7
6 mo	82–100	24–30	28–32	14.9–18.7
1 y	81–95	25–29	29–31	11.6–14.8
10 y	75–87	25–31	33–35	11.6–14.8
Adult male	85–95	28–32	33–35	11.6–14.8
Adult female	85–95	28–32	33–35	11.6–14.8

MCV = mean corpuscular volume; MCH = mean corpuscular hemoglobin; MCHC = mean corpuscular hemoglobin concentration; RDW = red blood cell distribution width.

DESCRIPTION & RATIONALE: Red blood cell (RBC) indices provide information about the mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), and RBC distribution width (RDW). The hematocrit, RBC count, and total hemoglobin tests are used to determine the RBC indices. MCV is determined by dividing the hematocrit by the total RBC count and is helpful in classifying anemias. MCH is determined by dividing the total hemoglobin concentration by the RBC count. MCHC is determined by dividing total hemoglobin by hematocrit. Hemoglobin content is indicated as normochromic, hypochromic, and hyperchromic. The RDW is a measurement of cell size distribution over the entire RBC population measured. It is an indication of anisocytosis, or excessive variations in cell size. Cell size is indicated as normocytic, microcytic, and macrocytic. (See

monographs titled "Hemoglobin," "Hematocrit," "Red Blood Cell Count," and "Red Blood Cell Morphology and Inclusions.") ■

INDICATIONS:

- Assist in the diagnosis of anemia
- Detect a hematologic disorder, neoplasm, or immunologic abnormality
- Determine the presence of a hereditary hematologic abnormality
- Monitor the effects of physical or emotional stress
- Monitor the progression of nonhematologic disorders such as chronic obstructive pulmonary disease, malabsorption syndromes, cancer, and renal disease
- Monitor the response to drugs or chemotherapy, and evaluate undesired reactions to drugs that may cause blood dyscrasias
- Provide screening as part of a complete blood count (CBC) in a general physical examination, especially upon admission to a health care facility or before surgery

RESULT

MCV increased in:

- Alcoholism
- Antimetabolite therapy
- Liver disease
- Pernicious anemia
- Vitamin B_{12}/folate anemia

MCV decreased in:

- Iron-deficiency anemia
- Thalassemias

MCH increased in:

- Macrocytic anemias

MCH decreased in:

- Hypochromic anemias
- Microcytic anemias

MCHC increased in:

- Thalassemia
- Spherocytosis

MCHC decreased in:

- Iron-deficiency anemia

RDW increased in:

- Anemias with heterogeneous cell size

RDW decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs and substances that may decrease the MCHC include styrene (occupational exposure).
- Drugs that may decrease the MCV include nitrofurantoin.
- Drugs that may increase the MCV include colchicine, pentamidine, pyrimethamine, and triamterene.
- Drugs that may increase the MCH and MCHC include oral contraceptives (long-term use).
- Diseases that cause agglutination of RBCs will alter test results.
- Cold agglutinins may falsely increase the MCV and decrease the RBC count. This can be corrected by warming the blood or diluting the sample with warmed saline and then correcting the RBC count mathematically.
- RBC counts can vary depending on the patient's position, decreasing when the patient is recumbent as a result of hemodilution and increasing when the patient rises as a result of hemoconcentration.
- Care in evaluating the CBC after transfusion should be taken into consideration.

- Venous stasis can falsely elevate RBC counts; therefore, the tourniquet should not be left on the arm for longer than 60 seconds.
- Failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.
- Hemolyzed or clotted specimens should be rejected.
- Lipemia and elevated white blood cell (WBC) count (greater than 50 WBC $\times 10^3/mm^3$ or 50,000/ mm^3) will falsely increase the hemoglobin measurement, also affecting the MCV and MCH.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to assess red blood cell shape and size.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal, hematopoietic, immune, and respiratory systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Gastrointestinal, Hematopoietic, Immune, and Respiratory System tables.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL lavender-top (EDTA) tube. An EDTA Microtainer sample may be obtained from infants, children, and adults for whom venipuncture may not be feasible. The specimen should be mixed gently by inverting the tube 10 times. It is stable when stored for up to 6 hours at room temperature or 24 hours if stored refrigerated. In addition, if it is anticipated that the specimen will not be analyzed within 4 to 6 hours, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 6 hours will contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and spherocytes, as well as necrobiotic WBCs.
- Remove the needle, and apply a pressure dressing over the puncture site.

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate healthcare practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include the other tests included in a CBC, erythropoietin, ferritin, iron/total iron-binding capacity, RBC morphology and inclusions, and reticulocyte count.

RED BLOOD CELL MORPHOLOGY AND INCLUSIONS

SYNONYM/ACRONYM: N/A.

SPECIMEN: Whole blood from one full lavender-top (EDTA) tube or Wright's-stained, thin-film peripheral blood smear. The laboratory should be consulted as to the necessity of thick-film smears for the evaluation of malarial inclusions.

REFERENCE VALUE: (Method: Microscopic, manual review of stained blood smear)

Red Blood Cell Morphology	Within Normal Limits	1+	2+	3+	4+
Size					
Anisocytosis	0–5+	5–10	10–20	20–50	Greater than 50
Macrocytes	0–5+	5–10	10–20	20–50	Greater than 50
Microcytes	0–5+	5–10	10–20	20–50	Greater than 50
Shape					
Poikilocytes	0–2+	3–10	10–20	20–50	Greater than 50

Stomatocytes	0–2+	2–10	10–20	20–50	Greater than 50
Drepanocytes (sickle cells)	Absent	Reported as present or absent			
Helmet cells	Absent	Reported as present or absent			
Agglutination	Absent	Reported as present or absent			
Rouleaux	Absent	Reported as present or absent			
Hemoglobin (Hgb) content					
Hypochromia	0–2+	3–10	10–50	50–75	Greater than 75
Polychromasia					
Adult	Less than 1+	2–5	5–10	10–20	Greater than 20
Newborn	1–6+	7–15	15–20	20–50	Greater than 50

Inclusions					
Cabot rings	Absent	Reported as present or absent			
Basophilic stippling	0–1+	1–5	5–10	10–20	Greater than 20
Howell-Jolly bodies	Absent	1–2	3–5	5–10	Greater than 10
Heinz bodies	Absent	Reported as present or absent			
Hgb C crystals	Absent	Reported as present or absent			
Pappenheimer bodies	Absent	Reported as present or absent			
Intracellular parasites (e.g., Plasmodium, Babesia, Trypanosoma)	Absent	Reported as present or absent			

DESCRIPTION & RATIONALE: The decision to manually review a peripheral blood smear for abnormalities in red blood cell (RBC) shape or size is made based on criteria established by the reporting laboratory. Cues in the results of the complete blood count (CBC) will point to specific abnormalities that can be confirmed visually, by microscopic review of the sample on a stained blood smear. ■

INDICATIONS:

- Assist in the diagnosis of anemia
- Detect a hematologic disorder, neoplasm, or immunologic abnormality
- Determine the presence of a hereditary hematologic abnormality
- Monitor the effects of physical or emotional stress on the patient
- Monitor the progression of nonhematologic disorders, such as chronic obstructive pulmonary disease, malabsorption syndromes, cancer, and renal disease
- Monitor the response to drugs or chemotherapy, and evaluate undesired reactions to drugs that may cause blood dyscrasias
- Provide screening as part of a CBC in a general physical examination, especially upon admission to a health care facility or before surgery

RESULT

Red Blood Cell Size

Cell size increased in:

- Alcoholism
- Aplastic anemia
- Chemotherapy
- Chronic hemolytic anemia
- Grossly elevated glucose (hyperosmotic)
- Hemolytic disease of the newborn
- Hypothyroidism
- Leukemia
- Lymphoma
- Metastatic carcinoma
- Myelofibrosis
- Myeloma
- Refractory anemia
- Sideroblastic anemia
- Vitamin B_{12}/folate deficiency

Cell size decreased in:

- Hemoglobin C disease
- Hemolytic anemias
- Hereditary spherocytosis
- Inflammation
- Iron-deficiency anemia
- Thalassemias

Red Blood Cell Shape

Variations in cell shape are the result of hereditary conditions such as elliptocytosis, sickle cell anemia, spherocytosis, thalassemias, or hemoglobinopathies (e.g., hemoglobin C disease). Irregularities in cell shape can also result from acquired conditions, such as physical/mechanical cellular trauma, exposure to chemicals, or reactions to medications.

- Acquired spherocytosis can result from Heinz body hemolytic anemia, microangiopathic hemolytic anemia, secondary isoimmunohemolytic anemia, and transfusion of old banked blood.
- Acanthocytes are associated with acquired conditions such as alcoholic cirrhosis with hemolytic anemia, disorders of lipid metabolism, hepatitis

of newborns, malabsorptive diseases, metastatic liver disease, the postsplenectomy period, and pyruvate kinase deficiency.

- Burr cells are commonly seen in acquired renal insufficiency, burns, cardiac valve disease, disseminated intravascular coagulation (DIC), hypertension, intravenous fibrin deposition, metastatic malignancy, normal neonatal period, and uremia.
- Codocytes are seen in hemoglobinopathies, iron-deficiency anemia, obstructive liver disease, and the postsplenectomy period.
- Dacryocytes are most commonly associated with metastases to the bone marrow, myelofibrosis, myeloid metaplasia, pernicious anemia, and tuberculosis.
- Schistocytes are seen in burns, cardiac valve disease, DIC, glomerulonephritis, hemolytic anemia, microangiopathic hemolytic anemia, renal graft rejection, thrombotic thrombocytopenic purpura, uremia, and vasculitis.

Red Blood Cell Hemoglobin Content

RBCs with a normal hemoglobin (Hgb) level have a clear central pallor and are referred to as *normochromic.*

- Cells with low Hgb and lacking in central pallor are referred to as *hypochromic.* Hypochromia is associated with iron-deficiency anemia, thalassemias, and sideroblastic anemia.
- Cells with excessive Hgb levels are referred to as *hyperchromic,* even though they technically lack a central pallor. Hyperchromia is usually associated with an elevated mean corpuscular Hgb concentration as well as hemolytic anemias.
- Cells referred to as *polychromic* are young erythrocytes that still contain ribonucleic acid (RNA). The RNA is picked up by the Wright's stain. Polychromasia is indicative of premature release of RBCs from bone marrow secondary to increased erythropoietin stimulation.

Red Blood Cell Inclusions

RBC inclusions can result from certain types of anemia, abnormal Hgb precipitation, or parasitic infection.

- Cabot rings may be seen in megaloblastic and other anemias, lead poisoning, and conditions in which RBCs are destroyed before they are released from bone marrow.
- Basophilic stippling is seen whenever there is altered Hgb synthesis, as in thalassemias, megaloblastic anemias, alcoholism, and lead or arsenic intoxication.
- Howell-Jolly bodies are seen in sickle cell anemia, other hemolytic anemias, megaloblastic anemia, congenital absence of the spleen, and the postsplenectomy period.
- Pappenheimer bodies may be seen in cases of sideroblastic anemia, thalassemias, refractory anemia, dyserythropoietic anemias, hemosiderosis, and hemochromatosis.
- Heinz bodies are most often seen in the blood of patients who have ingested drugs known to induce the formation of these inclusion bodies. They are also seen in patients with hereditary glucose-6-phosphate dehydrogenase (G6PD) deficiency.
- Hgb C crystals can often be identified in stained peripheral smears of patients with hereditary hemoglobin C disease.
- Parasites such as *Plasmodium* (transmitted by mosquitoes and causing malaria) and *Babesia* (transmitted by ticks), known to invade human RBCs, can be visualized with Wright's stain and other special stains of the peripheral blood.

CRITICAL VALUES:

The presence of sickle cells or parasitic inclusions should be brought to the immediate attention of the requesting health care practitioner.

INTERFERING FACTORS:

- Drugs and substances that may increase Heinz body formation as an initial precursor to significant hemolysis include acetanilid, acetylsalicylic acid, aminopyrine, antimalarials, antipyretics, furadaltone, furazolidone, methylene blue, naphthalene, and nitrofurans.
- Care in evaluating the CBC after transfusion should be taken into consideration.
- Leaving the tourniquet in place for longer than 60 seconds can falsely affect the results.
- Morphology can be evaluated to some extent via indices; therefore, failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.
- Hemolyzed or clotted specimens should be rejected.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assess red blood cell appearance.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular, gastrointestinal, hematopoietic, hepatobiliary, immune, musculoskeletal, and respiratory systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Cardiovascular, Gastrointestinal, Hematopoietic, Hepatobiliary, Immune, Musculoskeletal, and Respiratory System tables.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL lavender-top (EDTA) tube. An EDTA Microtainer sample may be obtained from infants,

children, and adults for whom venipuncture may not be feasible. The specimen should be mixed gently by inverting the tube 10 times. The specimen should be analyzed within 6 hours when stored at room temperature or within 24 hours if stored at refrigerated temperature. If it is anticipated the specimen will not be analyzed within 4 to 6 hours, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 6 hours will contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and spherocytes, as well as necrobiotic white blood cells.

- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Instruct patients to consume a variety of foods within the basic food groups, maintain a healthy weight, be physically active, limit salt intake, limit alcohol intake, and be a nonsmoker.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include the other tests included in a CBC, δ-aminolevulinic acid, biopsy of bone marrow, erythropoietin, ferritin, G6PD, hematocrit, hemoglobin, hemoglobin electrophoresis, iron/total iron-binding capacity, lead, platelet count, red blood cell count, red blood cell indices, reticulocyte count, and white blood cell count with differential.

REFRACTION

SYNONYMS/ACRONYMS: N/A.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION & RATIONALE: This noninvasive procedure tests the visual acuity of the eyes and determines abnormalities or refractive errors that need correction. Refractions are performed using a combination of different pieces of equipment. Refractive error can be quickly and accurately measured using computerized automatic refractors or manually with a viewing system consisting of an entire set of trial lenses mounted on a circular wheel (phoropter). A projector may also be used to display test letters and characters for use in assessing visual acuity. The retinoscope is probably the most valuable instrument that can be used to objectively assess visual acuity. It is also the only objective means of assessing refractive error in pediatric patients and patients who are unable to cooperate with other techniques of assessing refractive error due to illiteracy, senility, or inability to speak the same language as the examiner. Visual defects identified through refraction, such as hyperopia (farsightedness), in which the point of focus lies behid the retina; myopia (nearsightedness), in which the point of focus lies in front of the retina; and astigmatism, in which the refraction is unequal in diferent curvatures of the eyeball, can be corrected by glasses, contact lenses, or refractive surgery. ■

INDICATIONS:

- Determine if an optical defect is present and if light rays entering the eye focus correctly on the retina
- Determine the refractive error prior to refractive surgery (e.g., LASIK, LASEK) being performed
- Determine the type of corrective lenses needed for refractive errors, for example, biconvex or plus lenses for hyperopia, biconcave or minus lenses for myopia, compensatory lenses for astigmatism
- Diagnose refrative errors in vision

RESULT

Normal Findings:

- Normal visual acuity (with corrective lenses if appropriate).

Abnormal Findings:

- Refractive errors such as astigmatism, hyperopia, and myopia.

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with narrow-angle glaucoma if pupil dilation is performed, as dilation can initiate a severe and sight-threatening open-angle attack.
- Patients with allergies to mydriatics if pupil dilation using mydriatics is performed.

Factors that may impair the results of the examination:

- Improper pupil dilation may prevent adequate examination for refractive error.
- Inability of the patient to cooperate and remain still during the procedure because of age, significant pain, or mental status may interfere with the test results.
- Failure to follow medication restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

➤ Inform the patient that the procedure evaluates visual acuity.

- Obtain a history of the patient's complaints, including a list of known allergens, especially mydratics if dilation is to be performed.
- Obtain a history of the patient's known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit. For related diagnostic tests, refer to the table of tests associated with the Ocular System.
- Obtain a history of results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that mydriatics, if used, may cause blurred vision and sensitivity to light. There may also be a brief stinging sensation when the drop is put in the eye. Inform the patient that a technician, optometrist, or physician performs the test, in a quiet, darkened room, and that to evaluate both eyes, the test can take up 30 minutes (including time for the pupils to dilate before the test is actually performed).
- There are no food or fluid restrictions, unless by medical direction.
- The patient should withhold eye medications (particularly mydriatic eye drops if the patient has glaucoma) for at least 1 day prior to the test.
- Ensure that the patient understands that he or she must refrain from driving until the pupils return to normal (about 4 hours) after the test and has made arrangements to have someone else be responsible for transportation after the test.

Intratest:

- Ensure that the patient has complied with medication restrictions and pretesting preparations; assure that eye medications, especially mydriatics, have been restricted for at least 1 day prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- If dilation is to be performed, administer the ordered mydriatic to each eye and repeat in 5 to 15 minutes. Drops are placed in the eye with the patient looking up and the solution directed at the six o'clock position of the sclera (white of the eye) near the limbus (grey, semitransparent area of the eyeball where the cornea and sclera meet). The dropper bottle should not touch the eyelashes.
- Ask the patient to place the chin in the chin rest and gently press the forehead against the support bar. The examiner will sit about 2 feet away at eye level with the patient. The retinascope light is held in front of the eyes and directed through the pupil. Each eye is also examined for the characteristics of the red reflex, the reflection of the light from the retinascope, which normally moves in the same direction as the light.
- Request that the patient look straight ahead while the eyes are examined with the instrument and while different lenses are tried to provide the best corrective lenses to be prescribed. When optimal visual acuity is obtained with the trial lenses in each eye, a prescription for corrective lenses is written.
- The results are recorded manually or on a paper strip from the automated equipment for recall and postprocedure interpretation by the appropriate healthcare practitioner.

Post-test:

- Instruct the patient to resume usual medications, as directed by the health care practitioner.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss, perceived loss of driving privileges, or the possibility of requiring corrective lenses (self-image). Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Inform the patient that visual acuity and responses to light may change. Suggest that the patient wear dark glasses after the test until the pupils return to normal size. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include color perception test, intraocular muscle function, intraocular pressure, and slit-lamp biomicroscopy.

RENIN

SYNONYM/ACRONYM: Plasma renin activity (PRA).

SPECIMEN: Plasma (3 mL) collected in a lavender-top (EDTA) tube.

REFERENCE VALUE: (Method: Radioimmunoassay)

Age and Position	Conventional Units	SI Units (Conventional Units × 1)
Newborn Supine, normal sodium diet	2.0–35.0 ng/mL per hour	2.0–35.0 μg/L per hour

Age and Position	Conventional Units	SI Units (Conventional Units × 1)
1–12 mo	2.4–37.0 ng/mL per hour	2.4–37.0 μg/L per hour
1–3 y	1.7–112 ng/mL per hour	1.7–112 μg/L per hour
3–5 y	1.0–6.5 ng/mL per hour	1.0–6.5 μg/L per hour
5–10 y	0.5–5.9 ng/mL per hour	0.5–5.9 μg/L per hour
10–15 y	0.5–3.3 ng/mL per hour	0.5–3.3 μg/L per hour
Adult	0.2–1.6 ng/mL per hour	0.2–1.6 μg/L per hour
Upright, normal sodium diet		
Adult	0.7–3.3 ng/mL per hour	0.7–3.3 μg/L per hour

Values vary according to the laboratory performing the test, as well as the patient's age, gender, dietary pattern, state of hydration, posture, and physical activity.

DESCRIPTION & RATIONALE: Renin is an enzyme that activates the renin-angiotensin system. It is released into the renal veins by the juxtaglomerular apparatus in response to sodium depletion and hypovolemia. Renin converts angiotensinogen to angiotensin I. Angiotensin I is converted to angiotensin II, the biologically active form. Angiotensin II is a powerful vasoconstrictor that stimulates aldosterone production in the adrenal cortex. Angiotensin II and aldosterone increase blood pressure. Excessive amounts of angiotensin II cause renal hypertension. The renin assay screens for essential, renal, or renovascular hypertension. Plasma renin is expressed as the rate of angiotensin I formation per unit of time. The random collection of specimens without prior dietary preparations does not provide clinically significant information. Values should also be evaluated along with simultaneously collected aldosterone levels (see monographs titled "Aldosterone" and "Angiotensin-Converting Enzyme"). ■

INDICATIONS:

- Assist in the identification of primary hyperaldosteronism resulting from aldosterone-secreting adrenal adenoma
- Assist in monitoring patients on mineralocorticoid therapy
- Assist in the screening of the origin of essential, renal, or renovascular hypertension

RESULT

Increased in:

- Addison's disease
- Bartter's syndrome
- Cirrhosis
- Congestive heart failure
- Gastrointestinal disorders with electrolyte loss
- Hepatitis
- Hypokalemia
- Malignant hypertension
- Nephritis
- Nephropathies with sodium or potassium wasting
- Pheochromocytoma
- Pregnancy
- Renin-producing renal tumors
- Renovascular hypertension

Decreased in:

- Cushing's syndrome
- Essential hypertension
- Primary hyperaldosteronism

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase renin levels include albuterol, amiloride, azosemide, benazepril, bendroflumethiazide, captopril, chlorthalidone, cilazapril, cromakalim, desmopressin, diazoxide, dihydralazine, doxazosin, enalapril, endralazine, felodipine, fenoldopam, fosinopril, furosemide, hydralazine, hydrochlorothiazide, laxatives, lisinopril, lithium, methyclothiazide, metolazone, muzolimine, nicardipine, nifedipine, opiates, oral contraceptives, perindopril, ramipril, spironolactone, triamterene, and xipamide.
- Drugs and substances that may decrease renin levels include acetylsalicylic acid, angiotensin, angiotensin II, atenolol, bopindolol, bucindolol, carbenoxolone, carvedilol, clonidine, cyclosporin A, dexfenfluramine, glycyrrhiza, ibuprofen, indomethacin, levodopa, metoprolol, naproxen, nicardipine, nonsteroidal anti-inflammatory drugs, oral contraceptives, oxprenolol, propranolol, sulindac, and vasopressin.
- Upright body posture, stress, and strenuous exercise can increase renin levels.
- Recent radioactive scans or radiation can interfere with test results when radioimmunoassay is the test method.
- Diet can significantly affect results (e.g., low-sodium diets stimulate the release of renin).
- Hyperkalemia, acute increase in blood pressure, and increased blood volume may suppress renin secretion.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate hypertension.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine and genitourinary systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine and Genitourinary System tables.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient or family member that the position required (supine or upright) must be maintained for 2 hours before specimen collection. Inform the patient that multiple specimens may be required. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- The patient should be on a normal sodium diet (1 to 2 g sodium per day) for 2 to 4 weeks before the test.
- By medical direction, the patient should avoid diuretics, antihypertensive drugs, herbals, cyclic progestogens, and estrogens for 2 to 4 weeks before the test.

- Prepare an ice slurry in a cup or plastic bag to have ready for immediate transport of the specimen to the laboratory.

Intratest:

- Ensure that the patient has complied with diet and medication restrictions and pretesting dietary preparations; assure that specific medications have been restricted for at least 2 to 4 weeks prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Specify patient position (upright or supine) and exact source of specimen (peripheral vs. arterial). Perform a venipuncture after the patient has been in the upright (sitting or standing) position for 2 hours. If a supine specimen is requested on an inpatient, the specimen should be collected early in the morning before the patient rises. Collect the specimen in a 5-mL lavender-top (EDTA) tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- The sample should be placed in an ice slurry immediately after collection. Information on the specimen label can be protected from water in the ice slurry by first placing the specimen in a protective plastic bag. Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient to resume usual medications, as directed by the health care practitioner.
- *Nutritional considerations:* Instruct the patient to notify the requesting health care practitioner of any signs and symptoms of dehydration or fluid overload related to abnormal renin levels or compromised sodium regulatory mechanisms. Fluid loss or dehydration is signaled by the thirst response. Decreased skin turgor, dry mouth, and multiple longitudinal furrows in the tongue are symptoms of dehydration. Fluid overload may be signaled by a loss of appetite and nausea. Excessive fluid also causes pitting edema: When firm pressure is placed on the skin over a bone (e.g., the ankle), the indentation will remain after 5 seconds.
- *Nutritional considerations:* Educate patients of the importance of proper water balance. There is no recommended daily allowance (RDA) for water. Adults need 1 mL/kcal per day; infants need more because their basal metabolic heat production is much higher. In buildings with hard water, untreated tap water contains minerals such as calcium, magnesium, and iron. Water-softening systems replace these minerals with sodium, and therefore patients on a low-sodium diet should avoid drinking treated tap water and drink bottled water instead.
- *Nutritional considerations:* Renin levels affect the regulation of fluid balance and electrolytes. If appropriate, educate patients with low sodium levels that the major source of dietary sodium is found in table salt. Many foods, such as milk and other dairy products, are also good sources of dietary sodium. Most other dietary sodium is available through the consumption of processed foods. Patients on low-

sodium diets should be advised to avoid beverages such as colas, ginger ale, sports drinks, lemon-lime sodas, and root beer. Many over-the-counter medications, including antacids, laxatives, analgesics, sedatives, and antitussives, contain significant amounts of sodium. The best advice is to emphasize the importance of reading all food, beverage, and medicine labels. In 1989, the Subcommittee on the 10th Edition of the RDA established 500 mg as the recommended maximum daily intake for dietary intake of sodium. The requesting health care practitioner or nutritionist should be consulted before the patient on a low-sodium diet begins using salt substitutes. There are no RDAs established for potassium, but the estimated minimum intake for adults is 200 mEq/day. Potassium is present in all plant and animal cells, making dietary replacement fairly simple to achieve.

- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include aldosterone, angiotensin-converting enzyme, blood urea nitrogen, creatinine, kidney biopsy, blood and urine potassium, urine protein, blood and urine sodium, and urinalysis.

RENOGRAM

SYNONYMS/ACRONYM: Renocystography, renocystogram, radioactive renogram, renal scintigraphy.

AREA OF APPLICATION: Kidneys.

CONTRAST: Intravenous radioactive material.

DESCRIPTION & RATIONALE: A renogram is a nuclear medicine study performed to assist in diagnosing renal disorders, such as abnormal blood flow, collecting-system defects, and excretion dysfunction. Because renography uses no iodinated contrast medium, it is safe to use in patients who have iodine allergies or compromised renal function.

After intravenous administration of the radioisotope, information about the structures of the kidneys is obtained. The radioactive material is detected by a gamma camera, which can detect the gamma rays emitted by the radionuclide in the kidney. Renography simultaneously tracks the rate at which the radionuclide flows into *(vascular phase),* through *(tubular phase),* and out of *(excretory phase)* the kidneys. The times are plotted on a graph and compared to normal parameters of organ function. Differential estimates of left and right kidney contributions to glomerular filtration rate and effective renal plasma flow can be calculated. With the use of diuretic stimulation during the excretory phase, it is possible to differentiate between anatomic obstruction and nonobstructive residual dilation from previous hydronephrosis. All information obtained is stored in a computer to be used for further interpretation and computations. Renal function can be monitored by serially repeating this test and comparing results. ■

INDICATIONS:

- Aid in the diagnosis of renal artery embolism or renal infarction causing obstruction
- Aid in the diagnosis of renal artery stenosis resulting from renal dysplasia or atherosclerosis and causing arterial hypertension and reduced glomerular filtration rate
- Aid in the diagnosis of renal vein thrombosis resulting from dehydration in infants or obstruction of blood flow in the presence of renal tumors in adults
- Detect renal infectious or inflammatory diseases, such as acute or chronic pyelonephritis, renal abscess, or nephritis
- Determine the presence and effects of renal trauma, such as arterial injury, renal contusion, hematoma, rupture, arteriovenous fistula, or urinary extravasation
- Determine the presence, location, and cause of obstructive uropathy, such as calculi, neoplasm, congenital disorders, scarring, or inflammation
- Evaluate acute and chronic renal failure
- Evaluate chronic urinary tract infections, especially in children
- Evaluate kidney transplant for acute or chronic rejection
- Evaluate obstruction caused by stones or tumor

RESULT

Normal Findings:

- Normal shape, size, position, symmetry, vasculature, perfusion, and function of the kidneys
- Radionuclide material circulates bilaterally, symmetrically, and without interruption through the renal parenchyma, ureters, and urinary bladder, with 50% of the radionuclide excreted within the first 10 minutes

Abnormal Findings:

- Acute tubular necrosis
- Congenital anomalies (e.g., absence of a kidney)
- Decreased renal function
- Diminished blood supply
- Infection or inflammation (pyelonephritis, glomerulonephritis)
- Masses
- Obstructive uropathy
- Renal failure, infarction, cyst, or abscess
- Renal vascular disease, including renal artery stenosis or renal vein thrombosis
- Trauma

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Serum creatinine levels greater than or equal to 3 mg/dL (depending on the radionuclide used), which can decrease renal perfusion
- Other nuclear scans done within the previous 24 to 48 hours
- Medications such as antihypertensives, angiotensin-converting enzyme (ACE) inhibitors, and β-blockers taken within 24 hours of the test, which can affect the results (depending on the reason for the study)
- Dehydration, which can accentuate abnormalities; or overhydration, which can mask abnormalities
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images

Other considerations:

- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.
- Inaccurate timing of imaging after the radionuclide injection can affect the results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the renal system.
- Obtain a history of the patient's complaints and symptoms, including a list of known allergens.
- Obtain a history of the patient's genitourinary system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Genitourinary System table.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient's current medications.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Reassure the patient that radioactive material poses minimal radioactive hazard because of its short half-life and rarely produces side effects.

- Inform the patient that the procedure is performed in a special nuclear medicine department by a technologist and usually takes approximately 60 to 90 minutes, and that delayed images are needed 2 to 24 hours later. The patient may leave the department and return later to undergo delayed imaging.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.
- Inform the patient that he or she will be asked to drink several glasses of fluid before the study for hydration, unless the patient has a restricted fluid intake for other reasons.
- There are no food or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in a supine position on a flat table with foam wedges to help maintain position and immobilization.
- The radionuclide is administered intravenously, and the kidney area is scanned immediately with images taken every minute for 30 minutes.
- During the flow and static imaging, the diuretic furosemide (Lasix) or ACE inhibitor (captopril) can be administered intravenously and images obtained.
- Renogram curves can be plotted concurrently with flow studies in which blood flow is imaged and recorded as it occurs.
- Urine and blood laboratory studies are done after the renogram to correlate findings before diagnosis.
- If a study for vesicoureteral reflux is done, the patient is asked to void and a catheter is placed into the bladder. The radionuclide is instilled into the bladder, and multiple images are obtained during bladder filling. The patient is then requested to void, with the catheter in place or after catheter removal, depending on department policy. Imaging is continued during and after voiding. Reflux is determined by calculating the urine volume and counts obtained by imaging.
- Wear gloves during the radionuclide administration and while handling the patient's urine.
- The results are recorded on film or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Advise patient to drink increased amounts of fluids for 24 hours to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hours.
- Instruct the patient to flush the toilet immediately after each voiding following the procedure, and to wash hands meticulously with soap and water after each voiding for 24 hours after the procedure.
- Tell all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- Instruct the patient in the care and assessment of the injection site. Observe for bleeding, hematoma formation, and inflammation.

- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the spine, abdomen, or pelvis; intravenous pyelography; magnetic resonance imaging of the spine, abdomen or pelvis; and ultrasound of the abdomen.

RETICULOCYTE COUNT

SYNONYM/ACRONYM: Retic count.

SPECIMEN: Whole blood (1 mL) collected in lavender-top (EDTA) tube.

REFERENCE VALUE: (Method: Microscopic examination of specially stained peripheral blood smear or automated analyzer)

Age	Total Erythrocyte Count*
Newborn	3%–7%
1–12 mo	0.2%–2.8%
Adult	1.5%–2.5%

*Values are expressed as percentage of the red blood cell count

DESCRIPTION & RATIONALE: Normally, as it matures, the red blood cell (RBC) loses its nucleus. The remaining ribonucleic acid (RNA) will produce a characteristic color when special stains are used, making these cells easy to identify and enumerate. The presence of reticulocytes is an indication of the level of erythropoietic activity in the bone marrow. In abnormal conditions, reticulocytes are prematurely released into circulation. (See monographs titled "Red Blood Cell Count" and "Red Blood Cell Morphology and Inclusions.") ■

INDICATIONS:

- Evaluate erythropoietic activity
- Monitor response to therapy for anemias

RESULT: The reticulocyte production index (RPI) is a good estimate of RBC production. The calculation corrects the count for anemia and for the premature release of reticulocytes into the peripheral blood during periods of hemolysis or significant bleeding. The RPI also takes the maturation time of large polychromatophilic cells or nucleated RBCs seen on the peripheral smear into consideration:

RPI = % reticulocytes × [patient hematocrit (Hct)/normal Hct] × (1/maturation time)

As the formula shows, the RPI is inversely proportional to Hct, as follows:

Hematocrit (%)	Maturation Time (days)
45	1.0
35	1.5
25	2.0
15	2.5

Increased in:

- Blood loss
- Hemolytic anemias
- Iron-deficiency anemia
- Megaloblastic anemia

Decreased in:

- Alcoholism
- Anemia of chronic disease
- Aplastic anemia
- Bone marrow replacement
- Endocrine disease
- RBC aplasia
- Renal disease
- Sideroblastic anemia

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase reticulocyte counts include acetanilid, acetylsalicylic acid, amyl nitrate, antimalarials, antipyretics, antipyrine, arsenicals, corticotropin, dimercaprol, furaltadone, furazolidone, levodopa, methyldopa, nitrofurans, penicillin, procainamide, and sulfones.
- Drugs that may decrease reticulocyte counts include azathioprine, dactinomycin, hydroxyurea, methotrexate, and zidovudine.
- Reticulocyte count may be falsely increased by the presence of RBC inclusions (Howell-Jolly bodies, Heinz bodies, and Pappenheimer bodies) that stain with methylene blue.
- Reticulocyte count may be falsely decreased after a recent blood transfusion, as a result of the dilutional effect.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assess erythropoietic activity and monitor antianemic therapy.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic System table.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be

advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.

- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL lavender-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include biopsy of bone marrow, complete blood count, and RBC morphology and inclusions.

RETROGRADE URETEROPYELOGRAPHY

SYNONYM/ACRONYM: Retrograde.

AREA OF APPLICATION: Renal calyces, ureter.

CONTRAST: Radiopaque iodine-based contrast medium.

DESCRIPTION & RATIONALE: Retrograde ureteropyelography uses a contrast medium introduced through a ureteral catheter during cystography and radiographic visualization to view the renal collecting system (calyces, renal pelvis, and urethra). During a cystoscopic examination, a catheter is advanced through the ureters and into the kidney; contrast medium is injected through the catheter into the kidney. This procedure is primarily used in patients who are known to be hypersensitive to intravenously injected iodine-based contrast medium and when excretory ureterography does not adequately reveal the renal collecting system. The incidence of allergic reaction to the contrast medium is reduced because there is less systemic absorption of the contrast medium when injected into the kidney than when injected intravenously. Retrograde ureteropyelography sometimes provides more information about the anatomy of the different parts of the collecting system than can be obtained by excretory ureteropyelography. The procedure is not hampered by impaired renal function, but it carries the risk of urinary tract infection and sepsis. ■

INDICATIONS:

- Evaluate the effects of urinary system trauma
- Evaluate known or suspected ureteral obstruction
- Evaluate placement of a ureteral stent or catheter
- Evaluate the presence of calculi in the kidneys, ureters, or bladder
- Evaluate the renal collecting system when excretory urography is unsuccessful
- Evaluate space-occupying lesions or congenital anomalies of the urinary system
- Evaluate the structure and integrity of the renal collecting system

RESULT

Normal Findings:

- Normal outline and opacification of renal pelvis and calyces
- Normal size and uniform filling of the ureters

- Symmetrical and bilateral outline of structures

Abnormal Findings:

- Congenital renal or urinary tract abnormalities
- Hydronephrosis
- Neoplasms
- Obstruction as a result of tumor, blood clot, stricture, or calculi
- Obstruction of ureteropelvic junction
- Perinephric abscess
- Perinephric inflammation or suppuration
- Polycystic kidney disease
- Prostatic enlargement
- Tumor of the kidneys or the collecting system

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.
- Patients with renal insufficiency, indicated by a blood urea nitrogen value greater than 40 mg/dL, because contrast medium can complicate kidney function.
- Young patients (17 years old and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.
- Patients with multiple myeloma, who may experience decreased kidney function subsequent to administration of contrast medium.

Factors that may impair clear imaging:

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:

- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the renal collecting system.
- Obtain a history of the patient's complaints or symptoms, including a list of known allergens (especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, and dyes), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal and genitourinary systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Gastrointestinal and Genitourinary Systems tables.
- Note any recent procedures that can interfere with test results, including examinations using barium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a special department, usually in a radiology or vascular suite, by a health care provider and support staff, and takes approximately 30 to 60 minutes.
- Explain that an intravenous (IV) line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- Inform the patient that if a local anesthetic is used, the patient may feel (1) some pressure in the kidney area as the catheter is introduced and contrast medium injected, or (2) the urgency to void.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- The patient should fast and restrict fluids for 8 hours prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.
- Patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hours after the test. Failure to do so may result in lactic acidosis.

- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- Inform the patient that he or she may receive a laxative the night before the test, an enema, or a cathartic the morning of the test, as ordered.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*
- This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.

Intratest:

- Ensure that the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations for at least 8 hours prior to the procedure. Ensure the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs and assess neurologic status. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.
- Place patient on the table in a supine position in the lithotomy position.
- A kidney, ureter, and bladder (KUB) or plain film is taken to ensure that no barium or stool will obscure visualization of the urinary system. The patient may be asked to hold his or her breath to facilitate visualization.
- The patient is given a local anesthetic, and a cystoscopic examination is performed and the bladder is inspected.
- A catheter is inserted, and the renal pelvis is emptied by gravity. Contrast medium is introduced into the catheter. Inform the patient that the contrast medium may cause a temporary flushing of the face, a feeling of warmth, or nausea.
- X-ray exposures are made and the results processed. Inform the patient that additional views may be necessary to visualize the area in question.
- Additional contrast medium is injected through the catheter to outline the ureters as the catheter is withdrawn.
- Additional x-ray exposures are taken 10 to 15 minutes after the catheter is removed to evaluate retention of the contrast medium, indicating urinary stasis.
- The results are recorded manually, on film, or by automated equipment in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.
- The catheter may be kept in place and attached to a gravity drainage unit until urinary flow has returned or is corrected.

Post-test:

- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the health care practitioner. Renal function should be assessed before metformin is resumed.
- Monitor vital signs and neurologic status every 15 minutes for 1 hour, then every 2 hours for 4 hours, and then as ordered by the health care practitioner. Take temperature every 4 hours for 24 hours. Compare with baseline values. Notify the health care practitioner if temperature is elevated. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- Monitor for signs of sepsis and severe pain in the kidney area.
- Maintain the patient on adequate hydration after the procedure. Encourage the patient to drink lots of fluids to prevent stasis and to prevent the buildup of bacteria.
- *Nutritional considerations:* A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the abdomen, magnetic resonance imaging of the abdomen, renogram, and ultrasound of the kidney.

RHEUMATOID FACTOR

SYNONYMS/ACRONYMS: RF, RA.

SPECIMEN: Serum (1 mL) collected in a red-top tube

REFERENCE VALUE: (Method: Nephelometry) 0 to 20 IU/mL.

DESCRIPTION & RATIONALE: Individuals with rheumatoid arthritis harbor a macroglobulin-type antibody called *rheumatoid factor (RF)* in their blood. Patients with other diseases (e.g., systemic lupus erythematosus [SLE] and occasionally tuberculosis, chronic hepatitis, infectious mononucleosis, and subacute bacterial endocarditis) may also test positive for RF. RF antibodies are usually immunoglobulin (Ig) M but may also be IgG or IgA. ■

INDICATIONS: Assist in the diagnosis of rheumatoid arthritis, especially when clinical diagnosis is difficult

RESULT

Increased in:

- Chronic hepatitis
- Chronic viral infections
- Cirrhosis
- Dermatomyositis
- Infectious mononucleosis
- Leishmaniasis
- Leprosy
- Malaria
- Rheumatoid arthritis
- Sarcoidosis
- Scleroderma
- Sjögren's syndrome
- SLE
- Syphilis
- Tuberculosis
- Waldenström's macroglobulinemia

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Older patients may have higher values.
- Recent blood transfusion, multiple vaccinations or transfusions, or an inadequately activated complement may affect results.
- Serum with cryoglobulin or high lipid levels may cause a false-positive test and may require that the test be repeated after a fat-restriction diet.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the differential diagnosis and prognosis of arthritic diseases.

- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune and musculoskeletal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Musculoskeletal System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to anticipated chronic pain resulting from joint inflammation, impairment in mobility, musculoskeletal deformity, and loss of independence. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, as appropriate. Provide contact information, if desired, for the Arthritis Foundation *(http://www.arthritis.org)*.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Advise the patient, as appropriate, that additional studies may be undertaken to determine treatment regimen or to determine the possible causes of symptoms if the test is negative for rheumatoid arthritis. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be

performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

Related laboratory tests include antinuclear antibodies, C-reactive protein, erythrocyte sedimentation rate, synovial fluid analysis, and uric acid.

RUBELLA ANTIBODIES

SYNONYM/ACRONYM: German measles serology.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Indirect immunofluorescence) Immune or less than a fourfold increase in titer.

DESCRIPTION & RATIONALE: Rubella, commonly known as German measles, is a communicable viral disease transmitted by contact with respiratory secretions and aerosolized droplets of the secretions. The incubation period is 14 to 21 days. This disease produces a pink, macular rash that disappears in 2 to 3 days. Rubella infection induces immunoglobulin (Ig) G and IgM antibody production. This test can determine current infection or immunity from past infection. Rubella serology is part of the TORCH (*to*xoplasmosis, *r*ubella, *c*ytomegalovirus, and *h*erpes simplex type 2) panel routinely performed on pregnant women. Fetal infection during the first trimester can cause spontaneous abortion or congenital defects. Ideally the immune status of women of childbearing age should be ascertained before pregnancy, when vaccination can be administered to provide lifelong immunity. The presence of IgM antibodies indicates acute infection. The presence of IgG antibodies indicates current or past infection. Susceptibility to rubella is indicated by a negative reaction. Many laboratories use a qualitative assay that detects the presence of both IgM and IgG rubella antibodies. IgM- and IgG-specific enzyme immunoassays are also available to help distinguish acute infection from immune status. A rise in titer greater than fourfold in paired specimens is an indication of current infection. ■

INDICATIONS:

- Assist in the diagnosis of rubella infection
- Determine presence of rubella antibodies
- Determine susceptibility to rubella, particularly in pregnant women
- Perform as part of routine prenatal serologic testing

Result

Positive findings in: Rubella infection (past or present)

Critical Values:

Note and immediately report to the health care practitioner patients with a rubella-nonimmune status.

Interfering Factors: N/A

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to identify rubella infection or immunity.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of exposure to rubella.
- Obtain a history of the patient's immune and reproductive systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Reproductive System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm diagnosis. Any individual positive result should be repeated in 7 to 14 days to monitor a change in titer. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Vaccination considerations:* Record the date of the last menstrual period and determine the possibility of pregnancy prior to administration of rubella vaccine to female rubella-

nonimmune patients. Instruct patient not to become pregnant for 1 month after being vaccinated with the rubella vaccine to protect any fetus from contracting the disease and having serious birth defects. Instruct on birth control methods to prevent pregnancy, if appropriate. Delay rubella vaccination in pregnancy until after childbirth, and give immediately prior to discharge from the hospital.

- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and provide emotional support if results are positive and the patient is pregnant. Encourage the family to seek counseling if concerned with pregnancy termination. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Decisions regarding elective abortion should take place in the presence of both parents. Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks and difficulties of delivering and raising a developmentally challenged infant, as well as exploring other options (e.g., termination of pregnancy or adoption). Educate the patient regarding access to counseling services, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Instruct the patient in isolation precautions during time of communicability or contagion. Emphasize the need to return to have a convalescent blood sample taken in 7 to 14 days. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include cytomegalovirus, and *Toxoplasma*.

RUBEOLA ANTIBODIES

SYNONYM/ACRONYM: Measles serology.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Indirect immunofluorescence) Negative or less than a fourfold increase in titer.

DESCRIPTION & RATIONALE: Measles is caused by a single-stranded ribonucleic acid (RNA) paramyxovirus that invades the respiratory tract and lymphoreticular tissues. It is transmitted by respiratory secretions and

aerosolized droplets of the secretions. The incubation period is 10 to 11 days. Symptoms initially include conjunctivitis, cough, and fever. Koplik's spots develop 4 to 5 days later, followed by papular eruptions, body rash, and lymphadenopathy. The presence of immunoglobulin (Ig) M antibodies indicates acute infection. The presence of IgG antibodies indicates current or past infection. Susceptibility to measles is indicated by a negative reaction. Many laboratories use a qualitative assay that detects the presence of both IgM and IgG rubeola antibodies. IgM- and IgG-specific enzyme immunoassays are also available to help distinguish acute infection from immune status. A rise in titer greater than fourfold in paired specimens is an indication of current infection. ■

INDICATIONS:

- Determine resistance to or protection against measles virus
- Differential diagnosis of viral infection, especially in pregnant women with a history of exposure to measles

RESULT

Positive findings in:
Measles infection

CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to identify rubeola infection or immunity.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of exposure to measles.
- Obtain a history of the patient's immune and reproductive systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Reproductive System tables.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm the diagnosis. Any individual positive result should be repeated in 7 to 14 days to monitor a change in titer. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the

patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.

- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Instruct the patient in isolation precautions during time of communicability or contagion. Emphasize the need to return to have a convalescent blood sample taken in 7 to 14 days. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include rubella and varicella.

SCHIRMER TEAR TEST

SYNONYMS/ACRONYMS: N/A.

AREA OF APPLICATION: Eyelids.

CONTRAST: N/A.

DESCRIPTION & RATIONALE: The tear film, secreted by the lacrimal, Krause, and Wolfring glands, covers the surface of the eye. Blinking spreads tears over the eye and moves them toward an opening in the lower eyelid known as the punctum. Tears drain through the punctum into the nasolacrimal duct and into the nose. The Schirmer tear test simultaneously

tests both eyes to assess lacrimal gland function by determining the amount of moisture accumulated on standardized filter paper or strips, held against the conjuctial sac of each eye. The Schirmer test measures both reflex and basic secretion of tears. The Schirmer test number two measures basic tear secretion and is used to evaluate the accessory glands of Krause and Wolfring. The test is performed by instilling a topical anesthetic before insertion of filter paper. The topical anesthetic inhibits reflex tearing of major lacrimal glands produced by the filter paper, allowing testing of the accessory glands. ■

INDICATIONS:

- Assess adequacy of tearing for contact lens comfort
- Assess suspected tearing deficiency

RESULT

Normal Findings:

- 10 mm of moisture on test strip after 5 minutes. It may be slightly less than 10 mm in elderly patients.

Abnormal Findings:

- Tearing deficiency related to aging, dry eye syndrome, or Sjögren syndrome
- Tearing deficiency secondary to leukemia, lymphoma, or rheumatoid arthritis

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair the results of the examination:

- Inability of the patient to remain still and cooperative during the test may interfere with the test results.
- Rubbing or squeezing the eyes may affect results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure measures the secretion of tears.
- Obtain a history of the patient's complaints, including a list of known allergens, especially topical anesthetic eyedrops.
- Obtain a history of the patient's known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit. For related diagnostic tests, refer to the table of tests associated with the Ocular System.
- Obtain a history of results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.
- Review the procedure with the patient. Instruct the patient regarding the importance of keeping the eyes open for the test. Address concerns about pain related to the procedure. Explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Explain to the patient that some discomfort may be experienced after the test when the numbness wears off from anesthetic drops adminstered prior to the test. Inform the patient hat the test is

performed by a physician or optometrist and takes about 15 minutes to complete.

- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Seat the patient comfortably. Instruct the patient to look straight ahead, keeping the eyes open and unblinking.
- Instill topical anesthetic in each eye, as ordered, and provide time for it to work. Topical anesthetic drops are placed in the eye with the patient looking up and the solution directed at the six o'clock position of the sclera (white of the eye) near the limbus (grey, semitransparent area of the eyeball where the cornea and sclera meet). The dropper bottle should not touch the eyelashes. Insert a test strip in each eye. The strip should be folded over the midportion of both lower eyelids.
- The results are recorded manually for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Assess for corneal abraision caused by patient rubbing the eye before topical anesthetic has worn off.
- Instruct the patient to avoid rubbing the eyes for 30 minutes after the procedure.
- Instruct the patient not to reinsert contact lenses, if appropriate, for 2 hours.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of pain related to decreased lacrimation or inflammation. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- A related diagnostic test is slit-lamp biomicroscopy.

SEMEN ANALYSIS

SYNONYM/ACRONYM: N/A.

SPECIMEN: Semen from ejaculate specimen collected in a clean, dry, glass container known to be free of detergent. The specimen container should be kept at body temperature (37°C) during transportation.

REFERENCE VALUE: (Method: Macroscopic and microscopic examination)

Volume	2–5 mL
Color	White or opaque
Appearance	Viscous (pours in droplets, not clumps or strings)
Clotting and liquefaction	Complete in 20–30 minutes
pH	7.5–8.5
Sperm count	20–200 million/mL
Motility	At least 60%
Morphology	At least 70% normal oval-headed forms

DESCRIPTION & RATIONALE: Semen analysis is a valid measure of overall male fertility. Semen contains a combination of elements produced by various parts of the male reproductive system. Spermatozoa are produced in the testes and account for only a small volume of seminal fluid. Fructose and other nutrients are provided by fluid produced in the seminal vesicles. The prostate gland provides acid phosphatase and other enzymes required for coagulation and liquefaction of semen. Sperm motility depends on the presence of a sufficient level of ionized calcium. If the specimen has an abnormal appearance (e.g., bloody, oddly colored, turbid), the patient may have an infection. Specimens can be tested with a leukocyte esterase strip to detect the presence of white blood cells. ■

INDICATIONS:

- Assist in the diagnosis of azoospermia and oligospermia
- Evaluate infertility
- Evaluate vasectomy effectiveness
- Evaluate the effectiveness of vasectomy reversal
- Support or disprove sterility in paternity suit

RESULT: There is marked intraindividual variation in sperm count. Indications of suboptimal fertility should be investigated by serial analysis of two to three samples collected over several months. If abnormal results are obtained, additional testing may be requested.

Abnormality	Test Ordered	Normal Result
Decreased count	Fructose	Present (greater than 150 mg/dL)
Decreased motility with clumping	Male antisperm antibodies	Absent
Normal semen analysis with infertility	Female antisperm antibodies	Absent

Increased in: N/A

Decreased in:

- Hyperpyrexia
- Obstruction of ejaculatory system
- Orchitis
- Postvasectomy period
- Primary and secondary testicular failure
- Testicular atrophy (e.g., recovery from mumps)
- Varicocele

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs and substances that may decrease sperm count include arsenic, azathioprine, cannabis, cimetidine, cocaine, cyclophosphamide, estrogens, fluoxymesterone, ketoconazole, lead, methotrexate, methyltestosterone, nitrofurantoin, nitrogen mustard, procarbazine, sulfasalazine, and vincristine.
- Testicular radiation may decrease sperm counts.
- Cigarette smoking is associated with decreased production of semen.
- Caffeine consumption is associated with increased sperm density and number of abnormal forms.
- Delays in transporting the specimen and failure to keep the specimen warm during transportation are the most common reasons for specimen rejection.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the diagnosis of male infertility.
- Obtain a history of the patient's complaints, including a list of known allergens, and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune and reproductive system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Reproductive System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Note any recent procedures that can interfere with test results.
- Review the procedure with the patient. Instruct the patient to refrain from any sexual activity for 3 days before specimen collection. Instruct the patient to bring the specimen to the laboratory within 30 to 60 minutes of collection and to keep the specimen warm (close to body temperature) during transportation. The requesting health care practitioner usually provides the patient with instructions for specimen collection. Address concerns about pain related

to the procedure. Explain to the patient that there should be no discomfort during the procedure.

- *Sensitivity to social and cultural issues*, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

Ejaculated specimen:

- Ideally, the specimen is obtained by masturbation in a private location close to the laboratory. In cases in which the patient expresses psychological or religious concerns about masturbation, the specimen can be obtained during coitus interruptus, through the use of a condom, or through postcoital collection of samples from the cervical canal and vagina of the patient's sexual partner. The patient should be warned about the possible loss of the sperm-rich portion of the sample if coitus interruptus is the collection approach. If a condom is used, the patient must be carefully instructed to wash and dry the condom completely before use to prevent contamination of the specimen with spermicides.

Cervical vaginal specimen:

- Assist the patient to the lithotomy position on the examination table. A speculum is inserted, and the specimen is obtained by direct smear or aspiration of saline lavage.

Specimens collected from skin or clothing:

- Dried semen may be collected by sponging the skin with a gauze soaked in saline or soaking the material in a saline solution.

General:

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Provide a supportive, nonjudgmental environment when assisting a patient through the process of fertility testing. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Encourage the patient or family to seek counseling and other support services if concerned with infertility.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include antisperm antibodies, estradiol, and testosterone.

SICKLE CELL SCREEN

SYNONYM/ACRONYM: Sickle cell test.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

REFERENCE VALUE: (Method: Hemoglobin high-salt solubility) Negative.

DESCRIPTION & RATIONALE: The sickle cell screen is one of several screening tests for a group of hereditary hemoglobinopathies. The test is positive in the presence of rare sickling hemoglobin (Hgb) variants such as Hgb S and Hgb C Harlem. Hgb S results from an amino acid substitution during Hgb synthesis whereby valine replaces glutamic acid. Hemoglobin C Harlem results from the substitution of lysine for glutamic acid. Individuals with sickle cell disease have chronic anemia because the abnormal Hgb is unable to carry oxygen. The red blood cells of affected individuals are also abnormal in shape, resembling a crescent or sickle rather than the normal disk shape. This abnormality, combined with cell-wall rigidity, prevents the cells from passing through smaller blood vessels. Blockages in blood vessels result in hypoxia, damage, and pain. Individuals with the sickle cell trait do not have the clinical manifestations of the disease but may pass the disease on to children if the other parent has the trait (or the disease) as well. ■

INDICATIONS:

- Detect sickled red blood cells
- Evaluate hemolytic anemias

RESULT

Positive findings in:

- Combination of Hgb S with other hemoglobinopathies
- Hgb C Harlem anemia
- Sickle cell anemia
- Sickle cell trait
- Thalassemias

Negative findings in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase sickle cells in vitro include prostaglandins.
- A positive test does not distinguish between the sickle trait and sickle cell anemia; to make this determination, follow-up testing by Hgb electrophoresis should be performed.
- False-negative results may occur in children younger than 3 months of age.

- False-negative results may occur in patients who have received a recent blood transfusion before specimen collection, as a result of the dilutional effect.
- False-positive results may occur in patients without the trait or disease who have received a blood transfusion from a sickle cell–positive donor; this effect can last for 4 months after the transfusion.
- Test results are unreliable if the patient has pernicious anemia or polycythemia.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to determine the presence of hemoglobin S.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic system as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic System table.
- Note any recent procedures that can interfere with test results.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL lavender top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Advise the patient with sickle cell disease to avoid situations in which hypoxia may occur, such as strenuous exercise, staying at high

altitudes, or traveling in an unpressurized aircraft. Obstetric and surgical patients with sickle cell anemia are at risk for hypoxia and therefore require close observation: Obstetric patients are at risk for hypoxia during the stress of labor and delivery, and surgical patients may become hypoxic while under general anesthesia.

- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and and offer support, as appropriate. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Inform the patient that further testing may be indicated if results are positive. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include complete blood count, Hgb electrophoresis, red blood cell indices, and red blood cell morphology.

SLIT-LAMP BIOMICROSCOPY

SYNONYMS/ACRONYMS: Slit-lamp examination.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION & RATIONALE: This noninvasive procedure is used to visualize the anterior portion of the eye and its parts, including the eyelids and eyelashes, sclera, conjunctiva, cornea, iris, lens, and anterior chamber, and to detect pathology of any of these areas of the eyes. The slit lamp has a binocular microscope and light source that can be adjusted to examine the fluid, tissues, and structures of the eyes. Special attachments to the slit lamp are used for special studies and more detailed views of specific areas.

Dilating drops or mydriatics may be used to enlarge the pupil in order to allow the examiner to see the eye in greater detail. Mydriatics work either by temporarily paralyzing the muscle that makes the pupil smaller or by stimulating the iris dilator muscle. Patients with light-colored eyes (blue or hazel) will dilate faster than patients with dark eye color (brown). ■

INDICATIONS:

- Detect conjunctival and corneal injuries by foreign bodies and determine if ocular penetration or anterior chamber hemorrhage is present
- Detect corneal abrasions, ulcers, or abnormal curvatures (keratocoma)
- Detect deficiency in tear formation indicative of lacrimal dysfunction causing dry eye disease that can lead to corneal erosions or infection
- Detect lens opacities indicative of cataract formation
- Determine the presence of blepharitis, conjunctivitis, hordeolum, entropion, ectropian, trachoma, scleritis, and iritis
- Evaluate the fit of contact lenses

RESULT

Normal Findings:

- Normal anterior tissues and structures of the eyes

Abnormal Findings:

- Blepharitis
- Conjunctivitis
- Corneal abrasions
- Corneal ulcers
- Ectropian
- Entropian
- Hordeolum
- Iritis
- Keratoconus (abnormal curvatures)
- Lens opacities
- Scleritis
- Trachoma

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with narrow-angle glaucoma if pupil dilation is performed, as dilation can initiate a severe and sight-threatening open-angle attack.
- Patients with allergies to mydriatics if pupil dilation using mydriatics is performed.

Factors that may impair the results of the examination:

- Inability of the patient to cooperate and remain still during the procedure because of age, significant pain, or mental status may interfere with the test results.
- Failure to follow medication restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure detects abnormalities in the external and anterior eye structures.
- Obtain a history of the patient's complaints, including a list of known allergens, especially mydriatics if dilation is to be performed.
- Obtain a history of the patient's known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or

contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.

- Obtain a history of results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Instruct the patient to remove contact lenses or glasses, as appropriate, unless the study is being done to check the fit and effectiveness of the contact lenses. Instruct the patient regarding the importance of keeping the eyes open for the test.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that mydriatics, if used, may cause blurred vision and sensitivity to light. There may also be a brief stinging sensation when the drop is put in the eye. Inform the patient that an optometrist or physician performs the test, in a quiet, darkened room, and that to evaluate both eyes, the test can take up 30 minutes (including time for the pupils to dilate before the test is actually performed).
- There are no food or fluid restrictions, unless by medical direction.
- The patient should withhold eye medications (particularly mydriatic eye drops if the patient has glaucoma) for at least 1 day prior to the procedure.
- Ensure that the patient understands that he or she must refrain from driving until the pupils return to normal (about 4 hours) after the test and has made arrangements to have someone else be responsible for transportation after the test.

Intratest:

- Ensure that the patient has complied with medication restrictions and pretesting preparations; assure that eye medications, especially mydriatics, have been restricted for at least 1 day prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- Seat the patient comfortably. If dilation is to be performed, administer the ordered mydriatic to each eye and repeat in 5 to 15 minutes. Drops are placed in the eye with the patient looking up and the solution directed at the six o'clock position of the sclera (white of the eye) near the limbus (grey, semitransparent area of the eyeball where the cornea and sclera meet). The dropper bottle should not touch the eyelashes.
- Ask the patient to place the chin in the chin rest and gently press the forehead against the support bar.
- The physician or optometrist places the slit lamp in front of the patient's eyes in line with the examiner's eyes. The external structures of the eyes are inspected with the special bright light and microscope of the slit lamp. The light is then directed into the patient's eyes to inspect the anterior fluids and structures, and is adjusted for shape, intensity, and depth needed to visualize these areas. Magnification of the microscope is also adjusted to optimize visualization of the eye structures.
- Special attachments and procedures can also be used to obtain further diagnostic information about the eyes. These may include, for example, a camera to photograph specific parts, gonioscopy to determine anterior chamber closure, and a cobalt blue filter to detect minute corneal scratches, breaks, and abrasions with corneal staining.
- The results are recorded manually for recall and postprocedure interpre-

tation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual medications, as directed by the health care practitioner.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and encourage the family to recognize and be supportive of impaired activity related to vision loss, perceived loss of driving privileges, or the possibility of requiring corrective lenses (self-image). Discuss the implications of the abnormal test results on the patient's lifestyle.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Inform the patient that visual acuity and responses to light may change. Suggest that the patient wear dark glasses after the test until the pupils return to normal size. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include color perception test, fluorescein angiography, gonioscopy, intraocular pressure, intraocular muscle function, nerve fiber analysis, refraction, Schirmer tear test, and visual field testing.

SODIUM, BLOOD

SYNONYM/ACRONYM: Serum Na^+.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Ion-selective electrode)

Age	Conventional Units	SI Units (Conventional Units × 1)
Newborn	133–146 mEq/L	133–146 mmol/L
Infant	133–144 mEq/L	133–144 mmol/L
Child	135–145 mEq/L	135–145 mmol/L
Adult	135–145 mEq/L	135–145 mmol/L

DESCRIPTION & RATIONALE: Sodium is the most abundant cation in the extracellular fluid and, together with the accompanying chloride and bicarbonate anions, accounts for 92% of serum osmolality. Sodium plays a major role in maintaining homeostasis in a variety of ways, including maintaining the osmotic pressure of extracellular fluid, regulating renal retention and excretion of water, maintaining acid-base balance, regulating potassium and chloride levels, stimulating neuromuscular reactions, and maintaining systemic blood pressure. *Hypernatremia* (elevated sodium level) occurs when there is excessive water loss or abnormal retention of sodium. *Hyponatremia* (low sodium level) occurs when there is inadequate sodium retention or inadequate intake. ■

INDICATIONS:

- Determine whole-body stores of sodium, because the ion is predominantly extracellular
- Monitor the effectiveness of drug therapy, especially diuretics, on serum sodium levels

RESULT

Increased in:

- Azotemia
- Burns
- Cushing's disease
- Dehydration
- Diabetes
- Diarrhea (water loss in excess of salt loss)
- Excessive intake
- Excessive saline therapy
- Excessive sweating
- Fever
- Hyperaldosteronism
- Lactic acidosis
- Nasogastric feeding with inadequate fluid
- Vomiting

Decreased in:

- Central nervous system disease
- Congestive heart failure
- Cystic fibrosis
- Excessive antidiuretic hormone production
- Excessive use of diuretics
- Hepatic failure
- Hypoproteinemia
- Insufficient intake
- Intravenous (IV) glucose infusion
- Metabolic acidosis
- Mineralocorticoid deficiency (Addison's disease)
- Nephrotic syndrome

CRITICAL VALUES:

Hyponatremia: Less than 120 mmol/L

Hypernatremia: Greater than 160 mmol/L

Note and immediately report to the health care practitioner any critically increased or decreased values and related symptoms especially fluid imbalance.

Signs and symptoms of hyponatremia include confusion, irritability, convulsions, tachycardia, nausea, vomiting, and loss of consciousness. Possible interventions include maintenance of airway, monitoring for convulsions, fluid restriction, and performance of hourly neurologic checks. Administration of saline for replacement requires close attention to serum and urine osmolality.

Signs and symptoms of hypernatremia

include restlessness, intense thirst, weakness, swollen tongue, seizures, and coma. Possible interventions include treatment of the underlying cause of water loss or sodium excess, which includes sodium restriction and administration of diuretics combined with IV solutions of 5% dextrose in water (D_5W).

INTERFERING FACTORS:

- Drugs that may increase serum sodium levels include anabolic steroids, angiotensin, bicarbonate, carbenoxolone, cisplatin, corticotropin, cortisone, gamma globulin, and mannitol.
- Drugs that may decrease serum sodium levels include amphotericin B, bicarbonate, cathartics (excessive use), chlorpropamide, chlorthalidone, diuretics, ethacrynic acid, fluoxetine, furosemide, laxatives (excessive use), methyclothiazide, metolazone, nicardipine, quinethazone, theophylline (IV infusion), thiazides, and triamterene.
- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is present in the IV solution, falsely increasing the result.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate electrolyte balance.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine and genitourinary systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine and Genitourinary System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for

recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Evaluate the patient for signs and symptoms of dehydration. Decreased skin turgor, dry mouth, and multiple longitudinal furrows in the tongue are symptoms of dehydration. Dehydration is a significant and common finding in geriatric and other patients in whom renal function has deteriorated.
- *Nutritional considerations:* If appropriate, educate patients with low sodium levels that the major source of dietary sodium is found in table salt. Many foods, such as milk and other dairy products, are also good sources of dietary sodium. Most other dietary sodium is available through the consumption of processed foods. Patients on low-sodium diets should be advised to avoid beverages such as colas, ginger ale, sports drinks, lemon-lime sodas, and root beer. Many over-the-counter medications, including antacids, laxatives, analgesics, sedatives, and antitussives, contain significant amounts of sodium. The best advice is to emphasize the importance of reading all food, beverage, and medicine labels. In 1989, the Subcommittee on the 10th Edition of the RDA established 500 mg as the recommended maximum daily intake for dietary intake of sodium.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include aldosterone, anion gap, chloride, kidney stone analysis, blood and urine osmolality, blood and urine potassium, renin, and urine sodium.

SODIUM, URINE

SYNONYMS/ACRONYM: Urine Na^+

SPECIMEN: Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

REFERENCE VALUE: (Method: Ion-selective electrode)

Age	Conventional Units	SI Units (Conventional Units × 1)
6–10 y		
Male	41–115 mEq/24 h	41–115 mmol/24 h
Female	20–69 mEq/24 h	20–69 mmol/24 h
10–14 y		
Male	63–177 mEq/24 h	63–177 mmol/24 h
Female	48–168 mEq/24 h	48–168 mmol/24 h
Adult	27–287 mEq/24 h	27–287 mmol/24 h

Values vary markedly depending on dietary intake and hydration state.

DESCRIPTION & RATIONALE: Regulating electrolyte balance is a major function of the kidneys. In normally functioning kidneys, urine sodium levels increase when serum levels are high and decrease when serum levels are low to maintain homeostasis. Analyzing these urinary levels can provide important clues to the functioning of the kidneys and other major organs. There is diurnal variation in excretion of sodium, with values lower at night. Urine sodium tests usually involve timed urine collections over a 12- or 24-hour period. Measurement of random specimens may also be requested. ■

INDICATIONS:

- Determine potential cause of renal calculi
- Evaluate known or suspected endocrine disorder
- Evaluate known or suspected renal disease
- Evaluate malabsorption disorders

RESULT

Increased in:

- Adrenal failure
- Alkalosis
- Diabetes
- Diuretic therapy
- Excessive intake
- Renal tubular acidosis
- Salt-losing nephritis

Decreased in:

- Adrenal hyperfunction
- Congestive heart failure
- Diarrhea
- Excessive sweating
- Extrarenal sodium loss with adequate hydration
- Insufficient intake
- Postoperative period (first 24 to 48 hours)
- Prerenal azotemia
- Sodium retention (premenstrual)

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase urine sodium levels include acetazolamide, acetylsalicylic acid, amiloride, ammonium chloride, azosemide, benzthiazide, bumetanide, calcitonin, chlorothiazide, clopamide, cyclothiazide, diapamide, dopamine, ethacrynic acid, furosemide, hydrocortisone, hydroflumethiazide, isosorbide, levodopa, mercurial diuretics, methyclothiazide, metolazone, polythiazide, quinethazone, spironolac-

tone, sulfates, tetracycline, thiazides, torasemide, triamterene, trichlormethiazide, triflocin, verapamil, and vincristine.

- Drugs that may decrease urine sodium levels include aldosterone, anesthetics, angiotensin, corticosteroids, cortisone, etodolac, indomethacin, levarterenol, lithium, and propranolol.
- Sodium levels are subject to diurnal variation (output being lowest at night), which is why 24-hour collections are recommended.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate acute renal failure and acute oliguria, and to assist in the differential diagnosis of hyponatremia.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine and genitourinary systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine and Genitourinary System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
- Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- *Sensitivity to social and cultural issues*, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

Random specimen (collect in early morning):

Clean-catch specimen:

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse

the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.

- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling catheter:

- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 minutes before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Timed specimen:

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container's label the amount of urine, test start and stop times, and any foods or medications that can affect test results.

General:

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the health care practitioner.
- *Nutritional considerations:* If appropriate, educate patients with low sodium levels that the major source of dietary sodium is found in table salt. Many foods, such as milk and other dairy products, are also good sources of dietary sodium. Most other dietary sodium is available through the consumption of processed foods. Patients on low-sodium diets should be advised to avoid beverages such as colas, ginger ale, sports drinks, lemon-lime sodas, and root beer. Many over-the-counter medications, including antacids, laxatives, analgesics, sedatives, and antitussives, contain significant amounts of sodium. The best advice is to emphasize the importance of reading all food, beverage, and medicine labels. In 1989, the Subcommittee on the 10th Edition of the RDA established 500 mg as the recommended maximum daily intake for dietary intake of sodium.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.

- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include aldosterone, kidney stone analysis, blood and urine osmolality, blood and urine potassium, renin, and blood sodium.

SPONDEE SPEECH RECOGNITION THRESHOLD

SYNONYMS/ACRONYMS: SRT, Speech Reception Threshold.

AREA OF APPLICATION: Ears.

CONTRAST: N/A.

DESCRIPTION & RATIONALE: This noninvasive speech audiometric procedure measures the degree of hearing loss for speech. The speech recognition threshold is the lowest hearing level at which speech can barely be recognized or understood. In this test, a number of spondaic words are presented to the patient at different intensities. Spondaic words, or spondees, are words containing two syllables that are equally accented or emphasized when they are spoken to the patient. The SRT is defined as the lowest hearing level at which the patient correctly repeats 50% of a list of spondaic words. ■

INDICATIONS:

- Determine appropriate gain during hearing aid selection.
- Determine the extent of hearing loss related to speech recognition, as evidenced by the faintest level at which spondee words are correctly repeated.
- Differentiate a real hearing loss from pseudohypoacusis.
- Verify pure tone results.

Result

Normal Findings:

- Normal spondee threshold of about 6 to 10 dB of the normal pure tone threshold with 50% of the words pesented being correctly repeated at the appropriate intensity (see monograph titled "Audiometry, Hearing Loss")
- Normal speech recognition with 90% to 100% of the words presented being correctly repeated at an appropriate intensity

Abnormal Findings:

- Conductive hearing loss
- High-frequency hearing loss
- Sensorineural hearing loss (acoustic nerve impairment)

Critical Values: N/A

Interfering Factors:

Factors that may impair the results of the examination:

- Inability of the patient to cooperate or remain still during the procedure because of age or mental status may interfere with the test results.
- Unfamiliarity with the language the words are presented in or with the words themselves will alter the results.
- Improper placement of the earphones and inconsistency in frequency of word presentation will affect results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure measures hearing loss related to speech.
- Obtain a history of the patient's complaints, including a list of known allergens.
- Obtain a history of the patient's known or suspected hearing loss, including type and cause; ear conditions with treatment regimens; ear surgery; and other tests and procedures to assess and diagnose hearing deficit. For related diagnostic tests, refer to the table of tests associated with the Auditory System.
- Obtain a history of results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Ensure that the patient understands words and sounds in the language to be used for the test. Inform the patient that a series of words that change from loud to soft tones will be presented using earphones and that he or she will be asked to repeat the word. Explain that each ear is tested separately. Address concerns about pain related to the procedure. Explain to the patient that no discomfort will be experienced during the test. Inform the patient that an audiologist or other health care professional specializing in this area performs the test, in a quiet, soundproof room, and that the evaluation takes 5 to 10 minutes.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- Seat the patient on a chair in a soundproof booth. Place the earphones on the patient's head and

secure them over the ears. The audiometer is set at 20 dB above the known pure tone threshold obtained from audiometry (see monograph titled "Audiometry, Hearing Loss"). The test represents hearing levels at speech frequencies of 500, 1000, and 2000 Hz.

- The spondee words are presented to the ear with the best auditory response using a speech audiometer. The intensity is decreased and then increased to the softest sound at which the patient is able to hear the words and respond correctly to 50% of them. The procedure is then repeated for the other ear.
- The results are recorded manually for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of activity related to impaired hearing and perceived loss of independence. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- A related diagnostic test is hearing loss audiometry.

STEREOTACTIC BIOPSY, BREAST

SYNONYM/ACRONYM: N/A.

SPECIMEN: Breast tissue or cells.

REFERENCE VALUE: (Method: Macroscopic and microscopic examination of tissue) No abnormal cells or tissue.

DESCRIPTION & RATIONALE: A stereotactic breast biopsy is helpful when a mammogram or ultrasound examination shows a mass, a cluster of microcalcifications (tiny calcium deposits that are closely grouped

together), or an area of abnormal tissue change, usually with no lump being felt on a careful breast examination. A number of biopsy instruments and methods are utilized with x-ray guidance. They include core biopsy, which uses a large-bore needle to remove a generous sample of breast tissue, and a vacuum-assisted needle biopsy device. As an alternative to an open core surgical biopsy, which removes an entire breast lump for microscopic analysis, a narrow needle may be passed through the skin into the area under investigation. The is accomplished with the help of special breast x-rays. Images of the breast are obtained with a mammography machine, and the images are recorded in a computer. An initial x-ray locates the abnormality and two stereo views are obtained, each angled 15° to either side of the initial image. The computer calculates how much the area of interest has changed with each image and is able to determine the exact site in three-dimensional space. A small sample of breast tissue is obtained and can show whether the breast mass is cancerous or not. A pathologist examines the tissue that was removed and makes a final diagnosis to allow for effective treatment. ■

INDICATIONS:

- A mammogram showing a suspicious cluster of small calcium deposits
- A mammogram showing a suspicious solid mass that cannot be felt on breast examination
- Evidence of breast lesion by palpation, mammography, or ultrasound
- New mass or area of calcium deposits present at a previous surgery site
- Observable breast changes such as "peau d'orange" skin, scaly skin of the areola, drainage from the nipple, or ulceration of the skin
- Patient preference for a nonsurgical method of lesion assessment
- Structure of the breast tissue is distorted

RESULT: Positive findings in carcinoma of the breast

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- This procedure is contraindicated in patients with bleeding disorders.

Factors that may impair clear imaging:

- Failure to restrict food intake before the study
- Metallic objects within the examination field (e.g., jewelry, body rings, dental amalgams), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:

- Complications of the procedure include hemorrhage, infection at the insertion site, and cardiac arrhythmias.
- Failure to follow dietary restrictions

before the procedure may cause the procedure to be canceled or repeated.

- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses a breast mass.
- Obtain a history of the patient's complaints, including a list of known allergens, and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's reproductive system, as well as results of previously performed laboratory tests (especially coagulation tests and bleeding time), surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Reproductive System table.
- Note any recent procedures that can interfere with test results.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain will be experienced during the test, or there may be moments of discomfort. Inform the patient that the procedure is performed in special room, usually a mammography suite, by a health care practitioner and support staff and takes approximately 30 to 60 minutes.
- Explain that an intravenous (IV) line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- The patient should fast and restrict fluids for 8 hours prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.

Intratest:

- Ensure that the patient has complied with dietary and medication restrictions and pretesting preparations; assure that these have been restricted for at least 8 hours prior to the procedure. Ensure the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, date and time of collection, and site location (left or right breast).
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs and assess neurologic status. Protocols may vary from facility to facility.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia.
- Place the patient in the prone or sitting position on an exam table. Cleanse the selected area, and cover with a sterile drape.
- A local anesthetic is injected at the site, and a small incision is made or a needle inserted.
- Ask the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- Place tissue samples in properly labeled specimen containers, and promptly transport the specimens to the laboratory for processing and analysis.
- The results are recorded manually on x-ray film or electonically, in a computerized system, for recall and post-procedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet and medications, as directed by the health care practitioner.
- Monitor vital signs and neurologic status every 15 minutes for 1 hour, then every 2 hours for 4 hours, and then as ordered by the health care practitioner. Take temperature every 4 hours for 24 hours. Compare with baseline values. Notify the health care practitioner if temperature is elevated. Protocols may vary from facility to facility.
- Advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema.

- Instruct the patient in the care and assessment of the site. Observe for bleeding, hematoma formation, and inflammation. Note any pleuritic pain, persistent right shoulder pain, or abdominal pain.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of the potential perceived loss of body image. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic and laboratory tests include CA 15-3, carcinoembryonic antigen, estrogen and progesterone receptors, HER-2/neu oncoprotein, mammography, and ultrasound of the breast.

SYNOVIAL FLUID ANALYSIS

SYNONYMS/ACRONYM: Arthrocentesis, joint fluid analysis, knee fluid analysis.

SPECIMEN: Synovial fluid collected in a red-top tube for antinuclear antibodies (ANAs), complement, crystal examination, protein, rheumatoid factor (RF), and uric acid; sterile (red-top) tube for microbiologic testing; lavender-top (EDTA) tube for complete blood count (CBC) and differential; gray-top (sodium fluoride [NaFl]) tube for glucose; green-top (heparin) tube for lactic acid and pH.

REFERENCE VALUE: (Method: Macroscopic evaluation of appearance; spectrophotometry for glucose, lactic acid, protein, and uric acid; Gram stain, acid-fast stain, and culture for microbiology; microscopic examination of fluid for cell count and evaluation of crystals; ion-selective electrode for pH; nephelometry for RF and C3; indirect fluorescence for ANAs)

Color	Colorless to pale yellow
Clarity	Clear
Viscosity	High
ANA	Parallels serum level
C3	Parallels serum level
Glucose	Less than 10 mg/dL of blood level
Lactic acid	5–20 mg/dL
pH	7.2–7.4
Protein	Less than 3 g/dL
RF	Parallels serum level
Uric acid	Parallels serum level
Crystals	None present
RBC count	None
WBC count	Less than $0.2 \times 10^3/mm^3$ (or $200/mm^3$)
Neutrophils	Less than 25%
WBC morphology	No abnormal cells or inclusions
Gram stain and culture	No organisms present
AFB smear and culture	No AFB present

ANA = antinuclear antibodies; C3 = complement; RF = rheumatoid factor; RBC = red blood cell; WBC = white blood cell; AFB = acid-fast bacilli.

DESCRIPTION & RATIONALE: Synovial fluid analysis is performed via arthrocentesis, an invasive procedure involving insertion of a needle into the joint space. Synovial effusions are associated with disorders or injuries involving the joints. The most commonly aspirated joint is the knee, although samples also can be obtained from the shoulder, hip, elbow, wrist, and ankle, if clinically indicated. Joint disorders can be classified into five categories: noninflammatory, inflammatory, septic, crystal-induced, and hemorrhagic. ■

INDICATIONS:

- Assist in the evaluation of joint effusions
- Differentiate gout from pseudogout

RESULT

Fluid values increased in:

- *Acute bacterial infection:* White blood cell (WBC) count greater than $50 \times 10^3/mm^3$, marked predominance of neutrophils (greater than 90% neutrophils), positive Gram stain, positive cultures, possible presence of rice bodies, increased lactic acid, and complement levels paralleling those found in serum (may be elevated or decreased)
- *Gout:* WBC count variable; $0.5–200 \times 10^3/mm^3$ with a predominance of neutrophils (90% neutrophils), presence of monosodium urate crystals, increased uric acid, and complement levels paralleling those of serum (may be elevated or decreased)
- *Osteoarthritis, traumatic arthritis degenerative joint disease:* WBC count less than $3 \times 10^3/mm^3$ with less than 25%

neutrophils and the presence of cartilage cells

- *Pseudogout:* Presence of calcium pyrophosphate crystals
- *Rheumatoid arthritis:* WBC count 3–50 $\times$ $10^3/mm^3$ with a predominance of neutrophils (greater than 70% neutrophils), presence of ragocyte cells and possibly rice bodies, presence of cholesterol crystals if effusion is chronic, increased protein, increased lactic acid, and presence of rheumatoid factor
- *Systemic lupus erythematosus (SLE):* 3–50 $\times$ $10^3/mm^3$ with a predominance of neutrophils, presence of SLE cells, and presence of antinuclear antibodies
- *Trauma, joint tumors, or hemophilic arthritis:* Elevated RBC count, increased protein level, and presence of fat droplets (if trauma involved)
- *Tuberculous arthritis:* WBC count 2–100 $\times$ $10^3/mm^3$ with a predominance of neutrophils (up to 90% neutrophils), possible presence of rice bodies, presence of cholesterol crystals if effusion is chronic, in some cases a positive culture and smear for acid-fast bacilli (results frequently negative), and lactic acid

Fluid values decreased in (analytes in parentheses are decreased):

- Acute bacterial arthritis (glucose and pH)
- Gout (glucose)
- Rheumatoid arthritis (glucose, pH, and complement)
- SLE (glucose, pH, and complement)
- Tuberculous arthritis (glucose and pH)

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Blood in the sample from traumatic arthrocentesis may falsely elevate the RBC count.
- Undetected hypoglycemia or hyperglycemia may produce misleading glucose values.
- Refrigeration of the sample may result in an increase in monosodium urate crystals secondary to decreased solubility of uric acid; exposure of the sample to room air with a resultant loss of carbon dioxide and rise in pH encourages the formation of calcium pyrophosphate crystals.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to identify the presence and assist in the management of joint disease.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune and musculoskeletal systems, any bleeding disorders, and results of previously performed laboratory tests (especially bleeding time, complete blood count, partial thromboplastin time, platelets, and prothrombin time), surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Musculoskeletal System tables.
- Note any recent procedures that can interfere with test results.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of medications the patient is taking, including anticoagulant therapy, acetylsalicylic acid, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation. The requesting health care practitioner and laboratory should be advised if the patient

regularly uses these products so that their effects can be taken into consideration when reviewing results.

- Review the procedure with the patient. Inform the patient that it may be necessary to shave the site before specimen collection. Address concerns about pain related to the procedure. Explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to needle insertion through the joint space. Explain to the patient that any discomfort with the needle insertion will be minimized with local anesthetics and systemic analgesics. Explain that the anesthetic injection may cause an initial stinging sensation. Explain that, after the skin has been anesthetized, a large needle will be inserted through the joint space, and a "popping" sensation may be experienced as the needle penetrates the joint. Inform the patient that the procedure is performed under sterile conditions by a health care practitioner specializing in this procedure. The procedure usually takes approximately 20 minutes to complete.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no fluid restrictions unless by medical direction. Fasting for at least 12 hours before the procedure is recommended if fluid glucose measurements are included in the analysis. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that the patient has complied with dietary and medication restrictions and pretesting preparations; assure that food has been restricted for at least 12 hours prior to the procedure. Ensure that anticoagulant medications and aspirin have been withheld, as ordered.
- Assemble the necessary equipment, including an arthrocentesis tray with solution for skin preparation, local anesthetic, a 20-mL syringe, needles of various sizes, sterile drapes, and sterile gloves for the tests to be performed.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location, especially left or right.
- Assist the patient into a comfortable sitting or supine position, as appropriate.
- Prior to the administration of general or local anesthesia, shave and cleanse the site with an antiseptic solution, and drape the area with sterile towels.
- After the local anesthetic is administered, the needle is inserted at the collection site, and fluid is removed by syringe. Manual pressure may be applied to facilitate fluid removal.
- If medication is injected into the joint, the syringe containing the sample is detached from the needle and replaced with the one containing the drug. The medication is injected with gentle pressure. The needle is withdrawn, and digital pressure is applied to the site for a few minutes. If there is no evidence of bleeding, a sterile dressing is applied to the site. An elastic bandage can be applied to the joint.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- Place samples in properly labeled

specimen containers and promptly transport the specimens to the laboratory for processing and analysis. If bacterial culture and sensitivity tests are to be performed, record on the specimen containers any antibiotic therapy the patient is receiving.

- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet and medications, as directed by the health care practitioner.
- After local anesthesia, monitor vital signs and compare with baseline values. Notify the health care practitioner if temperature is elevated. Protocols may vary from facility to facility.
- Assess puncture site for bleeding, bruising, inflammation, and excessive drainage of synovial fluid approximately every 4 hours for 24 hours and daily thereafter for several days.
- Instruct the patient to report excessive pain, bleeding, or swelling to the requesting health care practitioner immediately. Report to health care practitioner if severe pain is present or the patient is unable to move the joint.
- Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the health care practitioner.
- Instruct the patient to apply an ice pack to the site for 24 to 48 hours.
- Administer antibiotics, as ordered, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Instruct the patient or caregiver to handle linen and dispose of dressings cautiously, especially if septic arthritis is suspected. Instruct the patient to avoid excessive use of the joint for several days to prevent pain and swelling. Instruct the patient to return for a follow-up visit as scheduled. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include rheumatoid factor and uric acid.

SYPHILIS SEROLOGY

SYNONYMS/ACRONYMS: Automated reagin testing (ART), fluorescent treponemal antibody testing (FTA-ABS), microhemagglutination–*Treponema pallidum* (MHA-TP), rapid plasma reagin (RPR), treponemal studies, Venereal Disease Research Laboratory (VDRL) testing.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Dark-field microscopy, rapid plasma reagin, enzyme-linked immunosorbent assay [ELISA], microhemagglutination, fluorescence) Nonreactive or absence of treponemal organisms.

DESCRIPTION & RATIONALE: There are numerous methods for detecting *Treponema pallidum,* the organism known to cause syphilis. Syphilis serology is routinely ordered as part of a prenatal workup and is required for evaluating donated blood units before release for transfusion. Selection of the proper testing method is important. Automated reagin testing (ART), rapid plasma reagin (RPR), and Venereal Disease Research Laboratory (VDRL) testing should be used for screening purposes. Fluorescent treponemal antibody testing (FTA-ABS) and microhemagglutination–*Treponema pallidum* (MHA-TP) are confirmatory methods for samples that screen positive or reactive. Cerebrospinal fluid should be tested only by the FTA-ABS method. Cord blood should not be submitted for testing by any of the aforementioned methods; instead, the mother's serum should be tested to establish whether the infant should be treated. ■

INDICATIONS:

- Monitor effectiveness of treatment for syphilis
- Screen for and confirm the presence of syphilis

RESULT

Positive or reactive findings in:

- Syphilis

False-positive or false-reactive findings in screening (RPR, VDRL) tests:

- Infectious:
  Bacterial endocarditis
  Chancroid
  Chickenpox
  Human immunodeficiency virus
  Infectious mononucleosis

Leprosy
Leptospirosis
Lymphogranuloma venereum
Malaria
Measles
Mumps
Mycoplasma pneumoniae
Pneumococcal pneumonia
Psittacosis
Relapsing fever
Rickettsial disease
Scarlet fever
Trypanosomiasis
Tuberculosis
Vaccinia (live or attenuated)
Viral hepatitis

- Noninfectious:

Advanced cancer
Advancing age
Chronic liver disease
Connective tissue diseases
Intravenous drug use
Multiple blood transfusions
Multiple myeloma and other immunologic disorders
Narcotic addiction
Pregnancy
False-positive or false-reactive findings in confirmatory (FTA-ABS, MHA-TP) tests:

- Infectious:

Infectious mononucleosis
Leprosy
Leptospirosis
Lyme disease
Malaria
Relapsing fever

- Noninfectious:

Systemic lupus erythematosus
Negative or nonreactive findings in: N/A

CRITICAL VALUES:

Note and immediately report to the health care practitioner positive results and related symptoms.

INTERFERING FACTORS: N/A

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to diagnose syphilis infection.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of exposure.
- Obtain a history of the patient's immune and reproductive systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Reproductive System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to cultural and social issues*, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should

be taken to avoid the use of equipment containing latex.

- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and offer support. Counsel the patient, as appropriate, regarding the risk of transmission and proper prophylaxis, and reinforce the importance of strict adherence to the treatment regimen. Inform the patient that positive findings must be reported to local health department officials, who will question him or her regarding sexual partners. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Inform the patient that repeat testing may be needed at 3-month intervals for 1 year to monitor the effectiveness of treatment. Answer any questions or address any concerns voiced by the patient or family.
- Offer support, as appropriate, to patients who may be the victim of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nonthreatening atmosphere for a discussion during which risks of sexually transmitted diseases are explained. It is also important to discuss problems the patient may experience (e.g., guilt, depression, anger).
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include acid phosphatase, *Chlamydia* group antibody, anal bacterial culture, Gram stain, hepatitis B, hepatitis C, human immunodeficiency virus, and β_2-microglobulin.

TESTOSTERONE, TOTAL

SYNONYM/ACRONYM: N/A.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Immunochemiluminometric assay [ICMA])

Age	Conventional Units	SI Units (Conventional Units × 0.0347)

I	2–23	2–10
II	5–70	5–30
III	15–280	10–30
IV	105–545	15–40
V	265–800	10–40

DESCRIPTION & RATIONALE: Testosterone is the major androgen responsible for sexual differentiation. In males, testosterone is made by the Leydig cells in the testicles and is responsible for spermatogenesis and the development of secondary sex characteristics. In females, the ovary and adrenal gland secrete small amounts of this hormone; however, most of the testosterone in females comes from the metabolism of androstenedione. In males, a testicular, adrenal, or pituitary tumor can cause an overabundance of testosterone, triggering precocious puberty. In females, adrenal tumors, hyperplasia, and medications can cause an overabundance of this hormone, resulting in masculinization or hirsutism. ■

INDICATIONS:

- Assist in the diagnosis of hypergonadism
- Assist in the diagnosis of male sexual precocity before age 10
- Distinguish between primary and secondary hypogonadism
- Evaluate hirsutism
- Evaluate male infertility

RESULT

Increased in:

- Adrenal hyperplasia
- Adrenocortical tumors
- Hirsutism
- Hyperthyroidism
- Idiopathic sexual precocity
- Polycystic ovaries
- Syndrome of androgen resistance
- Testicular or extragonadal tumors
- Trophoblastic tumors during pregnancy
- Virilizing ovarian tumors

Decreased in:

- Anovulation
- Cryptorchidism
- Delayed puberty
- Down syndrome
- Excessive alcohol intake
- Hepatic insufficiency
- Impotence
- Klinefelter's syndrome
- Malnutrition
- Myotonic dystrophy
- Orchiectomy
- Primary and secondary hypogonadism
- Primary and secondary hypopituitarism
- Uremia

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase testosterone levels include barbiturates, bromocriptine, cimetidine, flutamide, gonadotropin, levonorgestrel, mifepristone, moclobemide, nafarelin (males), nilutamide, oral contraceptives, rifampin, and tamoxifen.
- Drugs that may decrease testosterone levels include cyclophosphamide, cyproterone, danazol, dexamethasone, diethylstilbestrol, digoxin, D-Trp-6-LHRH, fenoldopam, goserelin, ketoconazole, leuprolide, magnesium sulfate, medroxyprogesterone, methylprednisone, nandrolone, oral contraceptives, pravastatin, prednisone, pyridoglutethimide, spironolactone, stanozolol, tetracycline, and thioridazine.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assess gonadal and adrenal function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine and reproductive systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine and Reproductive System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and and offer support, as appropriate. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be

performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

Related laboratory tests include dehydroepiandrosterone sulfate, follicle-stimulating hormone, luteinizing hormone, and semen analysis.

THYROGLOBULIN

SYNONYM/ACRONYM: Tg.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Chemiluminescent enzyme immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 1)
Cord blood	5–65 ng/mL	5–65 µg/L
1 d	6–93 ng/mL	6–93 µg/L
10 d	9–148 ng/mL	9–148 µg/L
Premature infant		
1 d	107–395 ng/mL	107–395 µg/L
3 d	49–163 ng/mL	49–163 µg/L
1 m	17–63 ng/mL	17–63 µg/L
7–12 y	20–50 ng/mL	20–50 µg/L
12–18 y	9–27 ng/mL	9–27 µg/L
Adult	0–50 ng/mL	0–50 µg/L

DESCRIPTION & RATIONALE: Thyroglobulin is an iodinated glycoprotein secreted by follicular epithelial cells of the thyroid gland. It is the storage form of the thyroid hormones thyroxine (T_4) and triiodothyronine (T_3). When thyroid hormones are released into the bloodstream, they split from thyroglobulin in response to thyroid-stimulating hormone. Values greater than 55 ng/mL are indicative of tumor recurrence in athyrotic patients. ■

INDICATIONS:

- Assist in the diagnosis of subacute thyroiditis
- Assist in the diagnosis of suspected disorders of excess thyroid hormone

- Management of differentiated or metastatic cancer of the thyroid
- Monitor response to treatment of goiter
- Monitor T_4 therapy in patients with solitary nodules

Result

Increased in:

- Differentiated thyroid cancer
- Graves' disease (untreated)
- Neonates
- Pregnancy
- Surgery or irradiation of the thyroid (elevated levels indicate residual or disseminated carcinoma)
- T_4-binding globulin deficiency
- Thyroiditis
- Thyrotoxicosis

Decreased in:

- Administration of thyroid hormone
- Congenital athyrosis (neonates)
- Thyrotoxicosis factitia

Critical Values: N/A

Interfering Factors:

- Drugs that may decrease thyroglobulin levels include neomycin and T_4.
- Autoantibodies to thyroglobulin can cause decreased values.
- Recent thyroid surgery or needle biopsy can interfere with test results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate thyroid gland function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine system as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine System table.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient is regularly using these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include T_4, free T_4, T_3, free T_3, and thyroid-stimulating hormone.

THYROID-BINDING INHIBITORY IMMUNOGLOBULIN

SYNONYMS/ACRONYM: Thyrotropin receptor antibodies, thyrotropin-binding inhibitory immunoglobulin, TBII.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Radioreceptor) Less than 10% inhibition. (*Note:* In patients with Graves' disease, inhibition is expected to be 10% to 100%.)

DESCRIPTION & RATIONALE: There are two functional types of thyroid receptor immunoglobulins: *thyroid-stimulating immunoglobulin (TSI)* and *thyroid-binding inhibitory immunoglobulin (TBII).* TSI reacts with the receptors, activates intracellular enzymes, and promotes epithelial cell activity that operates outside the feedback regulation for thyroid-stimulating

hormone (TSH) (see monograph titled "Thyroid-Stimulating Immunoglobulin"); TBII blocks the action of TSH and is believed to cause certain types of hyperthyroidism. These antibodies were formerly known as *long-acting thyroid stimulators.* High levels in pregnancy may have some predictive value for neonatal thyrotoxicosis: A positive result indicates that the antibodies are stimulating (TSI); a negative result indicates that the antibodies are blocking (TBII). TBII testing measures thyroid receptor immunoglobulin levels in the evaluation of thyroid disease. ■

INDICATIONS:

- Evaluate suspected acute toxic goiter
- Investigate suspected neonatal thyroid disease secondary to maternal thyroid disease
- Monitor hyperthyroid patients at risk for relapse or remission

RESULT

Increased in:

- Graves' disease
- Hyperthyroidism (various forms)
- Maternal thyroid disease
- Neonatal thyroid disease
- Toxic goiter

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Lithium may cause false-positive results.
- Recent radioactive scans or radiation within 1 week before the test can interfere with test results when radioimmunoassay is the test method.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate thyroid gland function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine system as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine System table.
- Note any recent procedures that can interfere with test results.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the

patient to breathe normally and to avoid unnecessary movement.

- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include thyroid-stimulating hormone (TSH) and thyroid-stimulating immunoglobulins.

THYROID SCAN

SYNONYMS/ACRONYM: Thyroid scintiscan, iodine thyroid scan, technetium thyroid scan.

AREA OF APPLICATION: Thyroid.

CONTRAST: Oral radioactive iodine or intravenous technetium-99m pertechnetate.

DESCRIPTION & RATIONALE: The thyroid scan is a nuclear medicine study performed to assess thyroid size, shape, position, and function; it is useful for evaluating thyroid nodules, multinodular goiter, and thyroiditis;

assisting in the differential diagnosis of masses in the neck, base of the tongue, and mediastinum; and ruling out possible ectopic thyroid tissue in these areas. Thyroid scanning is performed after oral administration of radioactive iodine-123 (I-123) or I-131, or intravenous (IV) injection of technetium-99m (Tc-99m). Increased or decreased uptake by the thyroid gland and surrounding area and tissue is noted: Areas of increased radionuclide uptake ("hot spots") are caused by hyperfunctioning thyroid nodules, which are usually nonmalignant; areas of decreased uptake ("cold spots") are caused by hypofunctioning nodules, which are more likely to be malignant. Ultrasound imaging may be used to determine if the cold spot is a solid, semicystic lesion or a pure cyst (cysts are rarely cancerous). To determine whether the cold spot depicts a malignant neoplasm, however, a biopsy must be performed. ■

INDICATIONS:

- Assess palpable nodules and differentiate between a benign tumor or cyst and a malignant tumor
- Assess the presence of a thyroid nodule or enlarged thyroid gland
- Detect benign or malignant thyroid tumors
- Detect causes of neck or substernal masses
- Detect forms of thyroiditis (e.g., acute, chronic, Hashimoto's)
- Detect thyroid dysfunction
- Differentiate between Graves' disease and Plummer's disease, both of which cause hyperthyroidism
- Evaluate thyroid function in hyperthyroidism and hypothyroidism (analysis combined with interpretation of laboratory tests, thyroid function panel including thyroxine and triiodothyronine, and thyroid uptake tests)

RESULT

Normal Findings:

- Normal size, contour, position, and function of the thyroid gland with homogeneous uptake of the radionuclide

Abnormal Findings:

- Adenoma
- Cysts
- Fibrosis
- Goiter
- Graves' disease (diffusely enlarged, hyperfunctioning gland)
- Hematoma
- Metastasis
- Plummer's disease (nodular hyperfunctioning gland)
- Thyroiditis (Hashimoto's)
- Thyrotoxicosis
- Tumors, benign or malignant

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus or mother

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Other nuclear scans done within the previous 24 to 48 hours
- Ingestion of foods containing iodine (iodized salt) or medications containing iodine (cough syrup, potassium iodide, vitamins, Lugol's solution, thyroid replacement medications), which can decrease the uptake of the radionuclide
- Antithyroid medications (propylthiouracil), corticosteroids, antihistamines, warfarin, sulfonamides, nitrates, corticosteroids, thyroid hormones, and isoniazid, which can decrease the uptake of the radionuclide
- Increased uptake of iodine in persons with an iodine-deficient diet or who are on phenothiazine therapy
- Vomiting and severe diarrhea, which can affect absorption of orally administered radionuclide
- Gastroenteritis, which can interfere with absorption of orally administered radionuclide
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images

Other considerations:

- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue can produce erroneous hot spots.
- Recent use of iodinated contrast medium for radiographic studies or recently performed nuclear medicine procedures can affect the uptake of the radionuclide.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses thyroid function and structure.
- Obtain a history of the patient's complaints and symptoms, including a list of known allergens.
- Obtain a history of the patient's endocrine system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Endocrine System table.
- All thyroid blood tests should be done before doing this test.
- All radiographic procedures done with iodinated contrast medium should be scheduled after this procedure and after radioactive iodine uptake is completed.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient's current medications.

- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Explain the purpose of the test and how the procedure is performed. Inform the patient that the procedure is performed in a nuclear medicine department, usually by a technologist and support staff, and takes approximately 30 to 60 minutes.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.
- The patient should fast for 8 to 12 hours prior to the procedure.
- There are no fluid or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with dietary restrictions and pretesting preparations; assure that food has been restricted for at least 8 to 12 hours. Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to lie still during the procedure because movement produces unclear images.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer sedative to a child or to an uncooperative adult, as ordered.
- Administer oral I-123 24 hours before scanning or IV technetium-99m 20 minutes before scanning. Place the patient in a supine position on a flat table. Scanning is performed over the anterior neck area.
- Wear gloves during the radionuclide administration and while handling the patient's urine.
- The results are recorded on film or by automated equipment in a computerized system for recall and post-procedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, as directed by the health care practitioner.
- Advise the patient to drink increased amounts of fluids for 24 to 48 hours to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hours.
- If a woman who is breast-feeding must have a nuclear scan, she should not breast-feed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- Instruct the patient to flush the toilet immediately after each voiding following the procedure, and to wash hands meticulously with soap and water after each voiding for 24 hours after the procedure.
- Tell all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor pro-

gression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include radioactive iodine uptake and ultrasound of the thyroid.

THYROID-STIMULATING HORMONE

SYNONYM/ACRONYM: Thyrotropin, TSH.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube; for a neonate, use filter paper.

REFERENCE VALUE: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 1)
Neonates–3 d	Less than 20 μIU/mL	Less than 20 mIU/L
Adults	0.4–4.2 μIU/mL	0.4–4.2 mIU/L

DESCRIPTION & RATIONALE: Thyroid-stimulating hormone (TSH) is produced by the pituitary gland in response to stimulation by thyrotropin-releasing hormone (TRH), a hypothalamic-releasing factor. TRH regulates the release and circulating levels of thyroid hormones in response to variables such as cold, stress, and increased metabolic need. Thyroid and pituitary function can be evaluated by TSH measurement. TSH exhibits diurnal variation, peaking between midnight and 4 a.m. and troughing between 5 and 6 p.m. TSH values are high at birth but reach adult levels in the first week of life. Elevated TSH levels combined with decreased thyroxine (T_4) levels indicate hypothyroidism and thyroid gland dysfunction. In general, decreased TSH and T_4 levels indicate secondary congenital hypothyroidism and pituitary hypothalamic dysfunction. A normal TSH level and a depressed T_4 level may indicate (1) hypothyroidism owing to a congenital defect in T_4-binding globulin, or (2) transient congenital hypothyroidism owing to hypoxia or prematurity. Early diagnosis and treatment in the neonate are crucial for the prevention of cretinism and mental retardation. ■

INDICATIONS:

- Assist in the diagnosis of congenital hypothyroidism
- Assist in the diagnosis of hypothy-

roidism or hyperthyroidism or suspected pituitary or hypothalamic dysfunction

- Differentiate functional euthyroidism from true hypothyroidism in debilitated individuals

Result

Increased in:

- Congenital hypothyroidism in the neonate (filter paper test)
- Ectopic TSH-producing tumors (lung, breast)
- Primary hypothyroidism
- Secondary hyperthyroidism owing to pituitary hyperactivity
- Thyroid hormone resistance
- Thyroiditis (Hashimoto's autoimmune disease)

Decreased in:

- Excessive thyroid hormone replacement
- Graves' disease
- Primary hyperthyroidism
- Secondary hypothyroidism (pituitary involvement)
- Tertiary hypothyroidism (hypothalamic involvement)

Critical Values: N/A

Interfering Factors:

- Drugs and hormones that may increase TSH levels include amiodarone, benserazide, erythrosine, flunarizine (males), iobenzamic acid, iodides, lithium, methimazole, metoclopramide, morphine, propranolol, radiographic agents, TRH, and valproic acid.
- Drugs and hormones that may decrease TSH levels include acetylsalicylic acid, amiodarone, anabolic steroids, carbamazepine, corticosteroids, dopamine, glucocorticoids, hydrocortisone, insulin-like growth factor-I, interferon-alfa-2b, iodamide, josamycin, levodopa, levothyroxine, methergoline, nifedipine, pyridoxine, T_4, and triiodothyronine (T_3).
- Failure to let the filter paper sample dry may affect test results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate thyroid gland function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine System table.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Filter paper test (neonate):

- Obtain kit and cleanse heel with antiseptic. Observe standard precautions, and follow the general guidelines in Appendix A. Use gauze to dry the stick area completely. Perform heel stick, gently squeeze infant's heel, and touch filter paper to the puncture site. Completely fill the circles on the filter paper, saturating the filter paper with blood. Apply pressure to the heel stick with a gauze pad to stop the bleeding. Allow the filter paper to dry thoroughly, label the specimen, and promptly transport it to the laboratory. Alternatively, if a specimen collection kit is used, follow instructions for labeling and mailing to the testing laboratory.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include adrenocorticotropic hormone, TRH stimulation test, T_4, free T_4, and T_3.

THYROID-STIMULATING IMMUNOGLOBULIN

SYNONYM/ACRONYM: Thyrotropin-receptor antibodies, TSI.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Animal cell transfection with luciferase marker) Less than 130% of basal activity.

DESCRIPTION & RATIONALE: There are two functional types of thyroid receptor immunoglobulins: *thyroid-stimulating immunoglobulin (TSI)* and *thyroid-binding inhibitory immunoglobulin (TBII).* TSI reacts with the receptors, activates intracellular enzymes, and promotes epithelial cell activity that operates outside the feedback regulation for thyroid-stimulating hormone (TSH); TBII blocks the action of TSH and is believed to cause certain types of hyperthyroidism (see monograph titled "Thyroid-Binding Immunoglobulin"). These antibodies were formerly known as *long-acting thyroid stimulators.* High levels in pregnancy may have some predictive value for neonatal thyrotoxicosis: A positive result indicates that the antibodies are stimulating (TSI); a negative result indicates that the antibodies are blocking (TBII). TSI testing measures thyroid receptor immunoglobulin levels in the evaluation of thyroid disease. ■

INDICATIONS:

- Follow-up to positive TBII assay in differentiating antibody stimulation from neutral or suppressing activity
- Monitor hyperthyroid patients at risk for relapse or remission

RESULT

Increased in: Graves' disease

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Lithium may cause false-positive TBII results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate thyroid gland function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine system as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For

related laboratory tests, refer to the Endocrine System table.

- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include thyroglobulin, thyroid-binding inhibitory immunoglobulin, and TSH.

THYROTROPIN-RELEASING HORMONE STIMULATION TEST

SYNONYM/ACRONYM: TRH stimulation.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Immunoassay) Minimal rise of 1 to 2 mIU/L above baseline; typical response is a 5- to 10-fold increase above baseline.

DESCRIPTION & RATIONALE: In the thyrotropin-releasing hormone (TRH) stimulation test, TRH is administered intravenously after collection of a baseline measurement of thyroid-stimulating hormone (TSH). Subsequent specimens are collected for TSH measurement at 30- and 60-minute intervals. An exaggerated response is an indication of abnormal thyroid gland function or disorders of the hypothalamic pituitary axis. Third-generation or "sensitive" TSH assays are now preferred over TRH stimulation. ■

INDICATIONS:

- Assist in the diagnosis and treatment of hypothalamic and pituitary disorders
- Differentiation of mania from schizophrenia

RESULT

Increased in:

- Pregnancy
- Primary hypothyroidism

Decreased in:

- Major depressive illnesses
- Primary hyperthyroidism
- Secondary hypothyroidism

CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate thyroid gland function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related labo-

ratory tests, refer to the Endocrine System table.

- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. The test should be performed in the morning because of the diurnal variation in TSH secretion. Inform the patient that multiple specimens will be collected. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Have emergency equipment readily available.
- Inform the patient that he or she may experience temporary nausea (mild), flushing, dizziness, peculiar taste, rise in blood pressure, and an urge to urinate as the infusion begins.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Begin intravenous infusion of 500 μg of protirelin (Thypinone), and collect specimens at 30- and 60-minute intervals.
- Monitor the patient's blood pressure if dizziness or other unusual symptoms are reported.
- Promptly transport the specimens to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include adrenocorticotropin hormone, follicle-stimulating hormone, growth hormone, luteinizing hormone, thyroxine, and free thyroxine.

THYROXINE-BINDING GLOBULIN

SYNONYM/ACRONYM: TBG.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Immunochemiluminometric assay [ICMA])

Age	Conventional Units	SI Units (Conventional Units × 10)
0–1 wk	3–8 mg/dL	30–80 mg/L
1–12 mo	1.6–3.6 mg/dL	16–36 mg/L
14 y–adult	1.2–2.5 mg/dL	12–25 mg/L
Adult	1.3–3.3 mg/dL	13–33 mg/L
Pregnancy, third trimester	4.7–5.9 mg/dL	47–59 mg/L
Oral contraceptives	1.5–5.5 mg/dL	15–55 mg/L

DESCRIPTION & RATIONALE: Thyroxine-binding globulin (TBG) is the predominant protein carrier for circulating thyroxine (T_4) and triiodothyronine (T_3). T_4-binding prealbumin and T_4-binding albumin are the other transport proteins. Conditions that affect TBG levels and binding capacity also affect free T_3 and free T_4 levels. ■

INDICATIONS:

- Differentiate elevated T_4 due to hyperthyroidism from increased TBG binding in euthyroid patients
- Evaluate hypothyroid patients
- Identify deficiency of or excess TBG due to hereditary abnormality

RESULT

Increased in:

- Acute intermittent porphyria
- Genetically high TBG
- Hypothyroidism
- Infectious hepatitis and other liver diseases
- Neonates
- Pregnancy

Decreased in:

- Acromegaly
- Chronic hepatic disease
- Genetically low TBG
- Major illness
- Marked hypoproteinemia, malnutrition
- Nephrotic syndrome
- Ovarian hypofunction
- Surgical stress
- Testosterone-producing tumors

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs and hormones that may increase TBG levels include estrogens, oral contraceptives, perphenazine, and tamoxifen.
- Drugs that may decrease TBG levels include anabolic steroids, androgens, asparaginase, corticosteroids, corticotropin, danazol, phenytoin, and propranolol.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate thyroid gland function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine system as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine System table.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process

and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include T_3, free T_3, T_4, and free T_4.

THYROXINE, FREE

SYNONYMS/ACRONYM: Free T_4, FT_4.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 12.9)
Newborn	0.8–2.8 ng/dL	10–36 pmol/L
1–12 mo	0.8–2.0 ng/dL	10–26 pmol/L
1–18 y	0.8–1.7 ng/dL	10–22 pmol/L
Adult	0.8–1.5 ng/dL	10–19 pmol/L

DESCRIPTION & RATIONALE: Thyroxine (T_4) is a hormone produced and secreted by the thyroid gland. Newborns are commonly tested for decreased T_4 levels by a filter paper method (see monograph titled "Thyroxine, Total"). Most T_4 in the serum (99.97%) is bound to thyroxine-binding globulin (TBG), prealbumin, and albumin. The remainder (0.03%) circulates as unbound or free T_4, which is the physiologically active form. Levels of free T_4 are proportional to levels of total T_4. The advantage of measuring free T_4 instead of total T_4 is that, unlike total T_4 measurements, free T_4 levels are not affected by fluctuations in TBG levels; as a result, free T_4 levels are considered the most accurate indicator of T_4 and its thyrometabolic activity. Free T_4 measurements are useful in evaluating thyroid disease when thyroid-stimulating hormone (TSH) levels alone provide insufficient information. Free T_4 and TSH levels are inversely proportional. Measurement of free T_4 is also recommended during treatment for hyper-

thyroidism, until symptoms have abated and levels have decreased into the normal range. ■

INDICATIONS:

- Evaluate signs of hypothyroidism or hyperthyroidism
- Monitor response to therapy for hypothyroidism or hyperthyroidism

RESULT

Increased in:

- Hyperthyroidism
- Hypothyroidism treated with T_4

Decreased in:

- Hypothyroidism
- Hypothyroidism treated with triiodothyronine (T_3)
- Pregnancy (late)

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase free T_4 levels include acetylsalicylic acid, amiodarone, halofenate, heparin, iopanoic acid, levothyroxine, methimazole, and radiographic agents.
- Drugs that may decrease free T_4 levels include amiodarone, anabolic steroids, asparaginase, methadone, methimazole, oral contraceptives, and phenylbutazone.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate thyroid gland function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine system as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine System table.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include antithyroglobulin and antithyroid peroxidase antibodies, thyroid-binding inhibitory immunoglobulin, thyroid-stimulating immunoglobulin, T_4, T_3, free T_3, and TSH.

THYROXINE, TOTAL

SYNONYMS/ACRONYM: T_4.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 12.9)
1–3 d	11.8–22.6 µg/dL	152–292 nmol/L

Over 60 y	5.0–10.7 μg/dL	65–138 nmol/L

DESCRIPTION & RATIONALE: Thyroxine (T_4) is a hormone produced and secreted by the thyroid gland. Newborns are commonly tested for decreased T_4 levels by a filter paper method. Most T_4 in the serum (99.97%) is bound to thyroxine-binding globulin (TBG), prealbumin, and albumin. The remainder (0.03%) circulates as unbound or free T_4, which is the physiologically active form. Levels of free T_4 are proportional to levels of total T_4. The advantage of measuring free T_4 instead of total T_4 is that, unlike total T_4 measurements, free T_4 levels are not affected by fluctuations in TBG levels; as a result, free T_4 levels are considered the most accurate indicator of T_4 and its thyrometabolic activity (see monograph titled "Thyroxine, Free"). ■

INDICATIONS:

- Evaluate signs of hypothyroidism or hyperthyroidism and neonatal screening for congenital hypothyroidism (required in all 50 states)
- Evaluate thyroid response to protein deficiency associated with severe illnesses
- Monitor response to therapy for hypothyroidism or hyperthyroidism

RESULT

Increased in:

- Acute psychiatric illnesses
- Excessive intake of iodine
- Hepatitis
- Hyperemesis gravidarum
- Hyperthyroidism
- Obesity
- Thyrotoxicosis due to Graves' disease
- Thyrotoxicosis factitia

Decreased in:

- Decreased TBG (nephrotic syndrome, liver disease, gastrointestinal protein loss, malnutrition)
- Hypothyroidism
- Panhypopituitarism
- Strenuous exercise

CRITICAL VALUES:

Hypothyroidism: Less than 2.0 μg/dL

Hyperthyroidism: Greater than 20.0 μg/dL

Note and immediately report to the health care practitioner any critically increased or decreased values and related symptoms.

At levels less than 2.0 μg/dL, the patient is at risk for myxedema

coma. Signs and symptoms of severe hypothyroidism include hypothermia, hypotension, bradycardia, hypoventilation, lethargy, and coma. Possible interventions include airway support, hourly monitoring for neurologic function and blood pressure, and administration of intravenous thyroid hormone.

At levels greater than 20.0 μg/dL, the patient is at risk for thyroid storm. Signs and symptoms of severe hyperthyroidism include hyperthermia, diaphoresis, vomiting, dehydration, and shock. Possible interventions include supportive treatment for shock, fluid and electrolyte replacement for dehydration, and administration of antithyroid drugs (propylthiouracil and Lugol's solution).

INTERFERING FACTORS:

- Drugs that may increase T_4 levels include amiodarone, amphetamines, corticosteroids, ether, fluorouracil, glucocorticoids, halofenate, insulin, iobenzamic acid, iopanoic acid, ipodate, levarterenol, levodopa, levothyroxine, opiates, oral contraceptives, phenothiazine, and prostaglandins.
- Drugs, substances, and treatments that may decrease T_4 levels include acetylsalicylic acid, aminoglutethimide, aminosalicylic acid, amiodarone, anabolic steroids, anticonvulsants, asparaginase, barbiturates, carbimazole, chlorpromazine, chlorpropamide, cholestyramine, clofibrate, cobalt, colestipol, corticotropin, cortisone, cotrimoxazole, cytostatic therapy, danazol, dehydroepiandrosterone, dexamethasone, diazepam, diazo dyes (e.g., Evans blue), dinitrophenol, ethionamide, fenclofenac, halofenate, hydroxyphenylpyruvic acid, interferon alfa-2b, iothiouracil, iron, isotretinoin, liothyronine, lithium, lovastatin, methimazole, methylthiouracil, mitotane, norethindrone, penicillamine, penicillin, phenylacetic acid derivatives, phenylbutazone, potassium iodide, propylthiouracil, reserpine, salicylate, sodium nitroprusside, stanozolol, sulfonylureas, tetrachlorothyronine, tolbutamide, and triiodothyronine (T_3).

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate thyroid gland function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine System table.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include adrenocorticotropic hormone, antithyroglobulin and antithyroid peroxidase antibodies, thyroid-binding inhibitory immunoglobulin, thyroid-stimulating hormone, thyroid-stimulating immunoglobulin, thyroxine-binding globulin, T_3, free T_3, and free T_4.

TOXOPLASMA ANTIBODY

SYNONYMS/ACRONYM: Toxoplasmosis serology, toxoplasmosis titer.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Indirect fluorescent antibody) Negative or less than a fourfold increase in titer.

DESCRIPTION & RATIONALE: Toxoplasmosis is a severe, generalized granulomatous central nervous system disease caused by the protozoan *Toxoplasma gondii.* Transmission to humans occurs by ingesting undercooked meat or handling contaminated matter such as cat litter. Immunoglobulin (Ig) M antibodies develop approximately 5 days after

infection and can remain elevated for 3 weeks to several months. IgG antibodies develop 1 to 2 weeks after infection and can remain elevated for months or years. *Toxoplasma* serology is part of the TORCH (*tox*oplasmosis, *r*ubella, *c*ytomegalovirus, and *h*erpes simplex type 2) panel routinely performed on pregnant women. Fetal infection during the first trimester can cause spontaneous abortion or congenital defects. Immunocompromised individuals are also at high risk for serious complications if infected. The presence of IgM antibodies indicates acute or congenital infection; the presence of IgG antibodies indicates current or past infection. ■

INDICATIONS:

- Assist in establishing a diagnosis of toxoplasmosis
- Document past exposure or immunity
- Serologic screening during pregnancy

RESULT

Positive findings in: *Toxoplasma* infection

CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the diagnosis of toxoplasmosis and to document history of previous exposure or immunity.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of exposure.
- Obtain a history of the patient's immune and reproductive systems, a history of other potential sources of exposure, and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Reproductive System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm the diagnosis. Any individual positive result should be repeated in 3 weeks to monitor a change in titer. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a

pressure dressing over the puncture site.

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and provide emotional support if results are positive and the patient is pregnant and/or immunocompromised. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Instruct the patient in isolation precautions during time of communicability or contagion. Emphasize the need to return to have a convalescent blood sample taken in 3 weeks. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include cytomegalovirus, fetal fibronectin, and rubella.

TRANSFERRIN

SYNONYM/ACRONYM: Siderophilin, TRF.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Nephelometry)

Age	Conventional Units	SI Units (Conventional Units × 0.01)
Newborn	130–275 mg/dL	1.3–2.75 g/L
Adult		
Male	215–365 mg/dL	2.2–3.6 g/L
Female	250–380 mg/dL	2.5–3.8 g/L

DESCRIPTION & RATIONALE: Transferrin is a glycoprotein formed in the liver. It transports circulating iron obtained from dietary intake and red blood cell breakdown. Transferrin carries 50% to 70% of the body's iron; normally it is approximately one-third saturated. Inadequate transferrin levels can lead to impaired hemoglobin synthesis and anemia. Transferrin is subject to diurnal variation, and it is responsible for the variation in levels of serum iron throughout the day. (See monograph titled "Iron-Binding Capacity [Total], Transferrin, and Iron Saturation.") ■

INDICATIONS:

- Determine the iron-binding capacity of the blood
- Evaluate iron metabolism in iron-deficiency anemia
- Evaluate nutritional status
- Screen for hemochromatosis

RESULT

Increased in:

- Iron-deficiency anemia

Decreased in:

- Acute or chronic infection
- Cancer (especially of the gastrointestinal tract)
- Excessive protein loss from renal disease
- Hepatic damage
- Hereditary atransferrinemia
- Malnutrition

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase transferrin levels include carbamazepine, danazol, mestranol, and oral contraceptives.
- Drugs that may decrease transferrin levels include cortisone and dextran.
- Transferrin levels are subject to diurnal variation and should be collected in the morning, when levels are highest.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to evaluate nutritional status (e.g., iron-deficiency anemia).
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic System table.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- Instruct the patient to fast for at least 12 hours before specimen collection.
- There are no fluid or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 12 hours prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe the venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient to resume usual diet, as directed by the health care practitioner.
- *Nutritional considerations:* Educate the patient with abnormal iron values that numerous factors affect the absorption of iron, enhancing or decreasing absorption regardless of the original content of the iron-containing dietary source. Consumption of large amounts of alcohol damages the intestine and allows increased absorption of iron. A high intake of calcium and ascorbic acid also increases iron absorption. Iron absorption after a meal is also increased by factors in meat, fish, or poultry. Iron absorption is decreased by the absence (gastric resection) or diminished presence (use of antacids) of gastric acid. Phytic acids from cereals, tannins from tea and coffee, oxalic acid from vegetables, and minerals such as copper, zinc, and manganese interfere with iron absorption.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include ferritin and iron/total iron-binding capacity.

TRIGLYCERIDES

SYNONYM/ACRONYM: Trigs, TG.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 0.0113)	
0–9 y			
Male	30–100 mg/dL	0.34–1.13 mmol/L	
Female	35–110 mg/dL	0.40–1.24 mmol/L	
10–20 y			
Male	32–148 mg/dL	0.36–1.67 mmol/L	
Female	37–124 mg/dL	0.42–1.40 mmol/L	
			Risk
Adult	Less than 150 mg/dL	Less than 1.70 mmol/L	Normal
	150–199 mg/dL	1.70–2.25 mmol/L	Borderline high
	200–499 mg/dL	2.26–5.64 mmol/L	High
	Greater than 500 mg/dL	Greater than 5.65 mmol/L	Very high

DESCRIPTION & RATIONALE: Triglycerides are a combination of three fatty acids and one glycerol molecule. They are necessary to provide energy for various metabolic processes. Excess triglycerides are stored in adipose tissue, and the fatty acids provide the raw materials needed for conversion to glucose (gluconeogenesis) or for direct use as an energy source. Although fatty acids originate in the diet, many are also derived from unused glucose and amino acids that the liver converts into stored energy. Triglyceride levels vary by age, sex, weight, and race:

- Levels increase with age.
- Levels are higher in men than in women (among women, those who take oral contraceptives have levels that are 20 to 40 mg/dL higher compared to those who do not).
- Levels are higher in overweight and obese populations com-

pared to those with normal weight.

Levels in African Americans are approximately 10 to 20 mg/dL lower compared to whites. ■

INDICATIONS:

- Evaluate known or suspected disorders associated with altered triglyceride levels
- Identify hyperlipoproteinemia (hyperlipidemia) in patients with a family history of the disorder
- Monitor the response to drugs known to alter triglyceride levels
- Screen adults who are either over 40 years of age or obese to estimate the risk for atherosclerotic cardiovascular disease

RESULT

Increased in:

- Acute myocardial infarction
- Alcoholism
- Anorexia nervosa
- Chronic ischemic heart disease
- Cirrhosis
- Glycogen storage disease
- Gout
- Hyperlipoproteinemia
- Hypertension
- Hypothyroidism
- Impaired glucose tolerance
- Metabolic syndrome
- Nephrotic syndrome
- Obesity
- Pancreatitis (acute and chronic)
- Pregnancy
- Renal failure
- Respiratory distress syndrome
- Stress
- Syndrome X (metabolic syndrome)
- Viral hepatitis
- Werner's syndrome

Decreased in:

- Brain infarction
- Chronic obstructive lung disease
- End-stage liver disease
- Hyperparathyroidism
- Hyperthyroidism
- Hypolipoproteinemia and abetalipoproteinemia
- Intestinal lymphangiectasia
- Malabsorption disorders
- Malnutrition

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase triglyceride levels include acetylsalicylic acid, aldatense, atenolol, bendroflumethiazide, cyclosporine, danazol, glucocorticoids, oral contraceptives, oxprenolol, pindolol, prazosin, propranolol, tamoxifen, and timolol.
- Drugs and substances that may decrease triglyceride levels include ascorbic acid, bezafibrate, captopril, carvedilol, celiprolol, chenodeoxycholic acid, cholestyramine, cilazapril, ciprofibrate, clofibrate, colestipol, dextrothyroxine, doxazosin, enalapril, eptastatin, fenofibrate, flaxseed oil, gemfibrozil, glucagon, halofenate, insulin, levonorgestrel, lovastatin, medroxyprogesterone, metformin, nafenopin, niacin, niceritrol, pinacidil, pindolol, pravastatin, prazosin, probucol, simvastatin, and verapamil.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate and monitor hyperlipidemia.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular and gastrointestinal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Cardiovascular and Gastrointestinal System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- The patient should fast for 12 hours before specimen collection. Ideally, the patient should be on a stable diet for 3 weeks and avoid alcohol consumption for 3 days before specimen collection.
- There are no fluid or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with dietary restrictions and other pretesting preparations; assure that food has been restricted for at least 12 hours prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe the venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient to resume usual diet, as directed by the health care practitioner.
- *Nutritional considerations:* Increased triglyceride levels may be associated with atherosclerosis and coronary artery disease. Nutritional therapy is recommended for individuals identified to be at high risk for developing coronary artery disease. If overweight, these patients should be encouraged to achieve a normal weight. The American Heart Association has Step 1 and Step 2 diets that may be helpful in achieving a goal of lowering total cholesterol and triglyceride levels. The Step 1 diet empha-

sizes a reduction in foods high in saturated fats and cholesterol. Red meats, eggs, and dairy products are the major sources of saturated fats and cholesterol. If triglycerides are also elevated, patients should be advised to eliminate or reduce alcohol and simple carbohydrates from their diet. The Step 2 diet recommends stricter reductions.

- *Social and cultural considerations:* Numerous studies point to the increased prevalence of excess body weight in American children and adolescents. Experts estimate that 25% of American children ages 6 to 11 years are obese. The medical, social, and emotional consequences of excess body weight are significant.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Special attention should be given to instructing the pediatric patient and caregiver regarding health risks and weight control. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association *(http://www.americanheart.org).*
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include antiarrhythmic drugs, apolipoprotein A, apolipoprotein B, aspartate aminotransferase, atrial natriuretic peptide, blood gases, B-type natriuretic peptide, blood calcium, ionized calcium, cholesterol (total, HDL, and LDL), C-reactive protein, creatine kinase and isoenzymes, glucose, glycated hemoglobin, homocysteine, ketones, lactate dehydrogenase and isoenzymes, lipoprotein electrophoresis, magnesium, myoglobin, potassium, and troponin.

TRIIODOTHYRONINE, FREE

SYNONYMS/ACRONYMS: Free T_3, FT_3.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 0.0154)
Children and adults	260–480 pg/dL	4.0–7.4 pmol/L
Pregnant women (4–9 mo gestation)	196–338 pg/dL	3.0–5.2 pmol/L

DESCRIPTION & RATIONALE: Unlike the thyroid hormone thyroxine (T_4), most T_3 is converted enzymatically from T_4 in the tissues rather than being produced directly by the thyroid gland (see monograph titled "Thyroxine, Total"). Approximately one-third of T_4 is converted to T_3. Most T_3 in the serum (99.97%) is bound to thyroxine-binding globulin (TBG), prealbumin, and albumin. The remainder (0.03%) circulates as unbound or free T_3, which is the physiologically active form. Levels of free T_3 are proportional to levels of total T_3. The advantage of measuring free T_3 instead of total T_3 is that, unlike total T_3 measurements, free T_3 levels are not affected by fluctuations in TBG levels. T_3 is four to five times more biologically potent than T_4. This hormone, along with T_4, is responsible for maintaining a euthyroid state. Free T_3 measurements are rarely required, but they are indicated in the diagnosis of T_3 toxicosis and when certain drugs are being administered that interfere with the conversion of T_4 to T_3. ■

INDICATIONS:

- Adjunctive aid to thyroid-stimulating hormone (TSH) and free T_4 assessment
- Assist in the diagnosis of T_3 toxicosis

RESULT

Increased in:

- High altitude
- Hyperthyroidism
- T_3 toxicosis

Decreased in:

- Hypothyroidism
- Malnutrition
- Nonthyroidal chronic diseases
- Pregnancy (late)

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase free T_3 include acetylsalicylic acid, amiodarone, and levothyroxine.
- Drugs that may decrease free T_3 include amiodarone, methimazole, phenytoin, propranolol, and radiographic agents.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assess thyroid gland function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine System table.
- Obtain a list of medications the

patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.

- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include total T_3, T_4, free T_4, and TSH.

TRIIODOTHYRONINE, TOTAL

SYNONYM/ACRONYM: T_3.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 0.0154)
1–3 d	100–740 ng/dL	1.54–11.40 nmol/L
1–12 mo	105–245 ng/dL	1.62–3.77 nmol/L
1–5 y	105–269 ng/dL	1.62–4.14 nmol/L
6–10 y	94–241 ng/dL	1.45–3.71 nmol/L
16–20 y	80–210 ng/dL	1.20–3.20 nmol/L
Adult	70–204 ng/dL	1.08–3.14 nmol/L
Pregnant woman (last 4 mo gestation)	116–247 ng/dL	1.79–3.80 nmol/L

DESCRIPTION & RATIONALE: Unlike the thyroid hormone thyroxine (T_4), most T_3 is converted enzymatically from T_4 in the tissues rather than being produced directly by the thyroid gland (see monograph titled "Thyroxine, Total"). Approximately one-third of T_4 is converted to T_3. Most T_3 in the serum (99.97%) is bound to thyroxine-binding globulin (TBG), prealbumin, and albumin. The remainder (0.03%) circulates as unbound or free T_3, which is the physiologically active form. Levels of free T_3 are proportional to levels of total T_3. The advantage of measuring free T_3 instead of total T_3 is that, unlike total T_3 measurements, free T_3 levels are not affected by fluctuations in TBG levels. T_3 is four to five times more biologically potent than T_4. This hormone, along with T_4, is responsible for maintaining a euthyroid state. ■

INDICATIONS: Adjunctive aid to thyroid-stimulating hormone (TSH) and free T_4 assessment

RESULT

Increased in:

- Conditions with increased TBG
- Early thyroid failure
- Hyperthyroidism
- Iodine-deficiency goiter
- Pregnancy
- T_3 toxicosis
- Thyrotoxicosis factitia
- Treated hyperthyroidism

Decreased in:

- Acute and subacute nonthyroidal disease
- Conditions with decreased TBG
- Hypothyroidism

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase total T_3 levels include amiodarone, amphetamine, benziodarone, clofibrate, fenoprofen, fluorouracil, halofenate, insulin, levothyroxine, methadone, opiates, oral con-

traceptives, phenytoin, prostaglandins, T_3, and valproic acid.

- Drugs that may decrease total T_3 levels include acetylsalicylic acid, amiodarone, anabolic steroids, asparaginase, carbamazepine, cholestyramine, clomiphene, colestipol, cotrimoxazole, dexamethasone, fenclofenac, furosemide, glucocorticoids, hydrocortisone, interferon alfa-2b, iobenzamic acid, iodides, ipodate, isotretinoin, lithium, methimazole, neomycin, netilmicin, oral contraceptives, penicillamine, phenobarbital, phenylacetic acid derivatives, phenylbutazone, phenytoin, potassium iodide, prednisone, propranolol, propylthiouracil, radiographic agents, salicylate, sodium ipodate, sulfonylureas, and tyropanoic acid.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assess thyroid gland function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine System table.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the

patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include free T_3, T_4, free T_4, and TSH.

TROPONINS I AND T

SYNONYMS/ACRONYMS: Cardiac troponin, cardiac troponin I (cTnI), cardiac troponin T (cTnT).

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable. Serial sampling is highly recommended. Care must be taken to use the same type of collection container if serial measurements are to be taken.

REFERENCE VALUE: (Method: Enzyme immunoassay)

Troponin I	Less than 0.35 ng/mL
Troponin T	Less than 0.20 μg/L

DESCRIPTION & RATIONALE: Troponin is a complex of three contractile proteins that regulate the interaction of actin and myosin. Troponin C is the calcium-binding subunit; it does not have a cardiac muscle–specific subunit. Troponin I and troponin T, however, do have cardiac muscle–specific subunits. They are detectable a few hours to 7 days after the onset of symptoms of myocardial damage. Troponin I is thought to be a more specific marker of cardiac damage than troponin T. Cardiac troponin I begins to rise 2 to 6 hours after myocardial infarction (MI). It has a biphasic peak: It initially peaks at 15 to 24 hours after MI and then exhibits a lower peak after 60 to 80 hours. Cardiac troponin T levels rise 2 to 6 hours after MI and remain elevated. Both proteins return to the reference range 7 days after MI. ■

INDICATIONS:

- Assist in establishing a diagnosis of MI
- Evaluate myocardial cell damage

Result

Increased in:

- Acute MI
- Minor myocardial damage
- Myocardial damage after coronary artery bypass graft surgery or percutaneous transluminal coronary angioplasty
- Unstable angina pectoris

Decreased in: N/A

Critical Values: N/A

Interfering Factors: N/A

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to identify and monitor cardiac injury.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular system and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Cardiovascular System table.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that a number of samples will be collected. Collection at time of admission, 2 to 4 hours, 6 to 8 hours, and 12 hours after admission are the minimal recommendations. Additional samples may be requested. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe the venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Increased troponin levels are associated with

coronary artery disease. Nutritional therapy is recommended for individuals identified to be at high risk for developing coronary artery disease. If overweight, these patients should be encouraged to achieve a normal weight. The American Heart Association has Step 1 and Step 2 diets that may be helpful in achieving a goal of lowering total cholesterol and triglyceride levels. The Step 1 diet emphasizes a reduction in foods high in saturated fats and cholesterol. Red meats, eggs, and dairy products are the major sources of saturated fats and cholesterol. If triglycerides are also elevated, patients should be advised to eliminate or reduce alcohol and simple carbohydrates from their diet. The Step 2 diet recommends stricter reductions.

- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association *(http://www.americanheart.org)*.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related laboratory tests include antiarrhythmic drugs, apolipoprotein A, apolipoprotein B, aspartate aminotransferase, atrial natriuretic peptide, blood gases, B-type natriuretic peptide, blood calcium, ionized calcium, cholesterol (total, HDL, and LDL), C-reactive protein, creatine kinase and isoenzymes, glucose, glycated hemoglobin, homocysteine, ketones, lactate dehydrogenase and isoenzymes, lipoprotein electrophoresis, magnesium, myoglobin, potassium, and triglycerides.

TUBERCULIN SKIN TESTS

SYNONYMS/ACRONYMS: TB tine test, PPD, Mantoux skin test.

SPECIMEN: N/A.

REFERENCE VALUE: (Method: Intradermal skin test) Negative.

DESCRIPTION & RATIONALE: Tuberculin skin tests are done to determine past or present exposure to tuberculosis. The multipuncture or tine test, a screening technique, uses either purified protein derivative (PPD) of tuberculin or old tuberculin. A positive response at the puncture site indicates cell-mediated immunity to the organism or a delayed hypersensitivity caused by interaction of the sensitized T lymphocytes. Verification of the patient's positive response to the multipuncture test is done with the more definitive Mantoux test using Aplisol or Tubersol administered by intradermal injection. The Mantoux test is the test of choice in symptomatic patients. It is also used in some settings as a screening test. A negative result is judged if there is no sign of redness or induration at the site of the injection or if the zone of redness and induration is less than 5 mm in diameter. A positive result is evidenced by an area of erythema and induration at the injection site that is greater than 10 mm. A positive result does not distinguish between active and dormant infection. A positive response to the Mantoux test is followed up with chest radiography and bacteriologic sputum testing to confirm diagnosis. ■

INDICATIONS:

- Evaluate cough, weight loss, fatigue, hemoptysis, and abnormal x-rays to determine if the cause of symptoms is tuberculosis
- Evaluate known or suspected exposure to tuberculosis, with or without symptoms, to determine if tuberculosis is present
- Evaluate patients with medical conditions placing them at risk for tuberculosis (e.g., acquired immunodeficiency syndrome, lymphoma, diabetes)
- Screen infants with the tine test at the time of first immunizations to determine tuberculosis exposure
- Screen populations at risk for developing tuberculosis (e.g., health care practitioners, nursing home residents, correctional facility personnel, prison inmates, and residents of the inner city living in poor hygienic conditions)

RESULT

Positive findings in: Pulmonary tuberculosis

CRITICAL VALUES:

Note and immediately report to the health care practitioner positive results and related symptoms.

INTERFERING FACTORS:

- Drugs such as immunosuppressive agents or steroids can alter results.
- Diseases such as hematologic cancers or sarcoidosis can alter results.
- Recent or present bacterial, fungal, or viral infections may affect results. False-positive results may be caused by the presence of nontuberculous mycobacteria or by serial testing.
- False-negative results can occur if sensitized T cells are temporarily decreased. False-negative results also can occur in the presence of bacterial infections, immunologic deficiencies, immunosuppressive agents, live-virus vaccinations (e.g., measles, mumps, varicella, rubella), malnutrition, old age, overwhelming tuberculosis, renal failure, and active viral infections (e.g., chickenpox, measles, mumps).
- Improper storage of the tuberculin solution (e.g., with respect to temperature, exposure to light, and stability on opening) may affect the results.

- Improper technique when performing the intradermal injection (e.g., injecting into subcutaneous tissue) may cause false-negative results.
- Incorrect amount or dilution of antigen injected or delayed injection after drawing the antigen up into the syringe may affect the results.
- Incorrect reading of the measurement of response or timing of the reading may interfere with results.
- ⚠ It is not known whether the test has teratogenic effects or reproductive implications; the test should be administered to pregnant women only when clearly indicated.
- ⚠ The test should not be administered to a patient with a previously positive tuberculin skin test because of the danger of severe reaction, including vesiculation, ulceration, and necrosis.
- The test does not distinguish between current and past infection.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to indicate exposure to tuberculosis.
- Obtain a history of the patient's complaints, including a list of known allergens, and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's immune and respiratory systems and results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. Obtain a history of tuberculosis or tuberculosis exposure, signs and symptoms indicating possible tuberculosis, and other skin test or vaccinations and sensitivities. For related laboratory tests, refer to the Immune and Respiratory System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Ensure that the patient does not currently have tuberculosis and has not had a positive skin test previously before beginning the test. Do not administer the test if the patient has a skin rash or other eruptions at the test site. Inform the patient that the procedure takes approximately 5 minutes. Address concerns about pain related to the procedure. Explain to the patient that that a moderate amount of pain may be experienced when the intradermal injection is performed.
- Emphasize to the patient that the area should not be scratched or disturbed after the injection and before the reading.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- Have epinephrine hydrochloride solution (1:1000) available in the event of anaphylaxis.

- Cleanse the skin site on the lower anterior forearm with alcohol swabs and allow to air-dry.

Multipuncture test:

- Remove the cap covering the tines and stretch the forearm skin taut. Firmly press the device into the prepared site, hold it in place for 1 second, and then remove it. Four punctures should be visible. Record the site, and remind the patient to return in 48 to 72 hours to have the test read. At the time of the reading, use a plastic ruler to measure the diameter of the largest indurated area, making sure the room is sufficiently lighted to perform the reading. A palpable induration greater than or equal to 2 mm at one or more of the punctures indicates a positive test result.

Mantoux (intradermal) test:

- Prepare PPD or old tuberculin in a tuberculin syringe with a short, 26-gauge needle attached. Prepare the appropriate dilution and amount for the most commonly used intermediate strength (5 tuberculin units in 0.1 mL) or a first strength usually used for children (1 tuberculin unit in 0.1 mL). Inject the preparation intradermally at the prepared site as soon as it is drawn up into the syringe. When properly injected, a bleb or wheal 6 to 10 mm in diameter is formed within the layers of the skin. Record the site, and remind the patient to return in 48 to 72 hours to have the test read. At the time of the reading, use a plastic ruler to measure the diameter of the largest indurated area, making sure the room is sufficiently lighted to perform the reading. Palpate for thickening of the tissue; a positive result is indicated by a reaction of 5 mm or more with erythema and edema.

General:

- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Emphasize to the patient the need to return and have the test results read within the specified time frame of 48 to 72 hours after injection. Inform the patient that the effects from a positive response at the site can remain for 1 week. Educate the patient that a positive result may put him or her at risk for infection related to impaired primary defenses, impaired gas exchange related to decrease in effective lung surface, and intolerance to activity related to an imbalance between oxygen supply and demand. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include relevant acid-fast cultures and smears.

TUNING FORK TESTS

SYNONYMS/ACRONYMS: Bing test, Rinne test, Schwabach test, Weber test.

AREA OF APPLICATION: Ears.

CONTRAST: N/A.

DESCRIPTION & RATIONALE: These noninvasive assessment procedures are done to distinguish conduction hearing loss from sensorineural hearing loss. They may be performed as part of the physical assessment examination and followed by hearing loss audiometry for confirmation of questionable results. The tuning forks tests described in this monograph are named for the four German otologists who described their use. Tuning forks tests are used less frequently by audiologists in favor of more sophisticated electronic methods, but presentation of the tuning fork test methodology is useful to illustrate the principles involved in electronic test methods.

A tuning fork is a bipronged metallic device that emits a clear tone at a particular pitch when it is set into vibration by holding the stem in the hand and striking one of the prongs or tines against a firm surface. The Bing test samples for conductive hearing loss by intermittently occluding and unblocking the opening of the ear canal while holding a vibrating tuning fork to the mastoid process behind the ear. The occlusion effect is absent in patients with conductive hearing loss and is present in patients with normal hearing or with sensorineural hearing loss. The Rinne test compares the patients' own hearing by bone conduction to their hearing by air conduction to determine whether hearing loss, if detected, is conductive or sensorineural. The Schwabach test compares the patient's level of bone conduction hearing to that of a presumed normal-hearing examiner. The Weber test has been modified by many audiologists for use with electronic equipment. When the test is administered, the patient is asked to tell the examiner the location of the tone heard (left ear, right ear, both ears, or midline) in order to determine whether the hearing loss is conductive, sensorineural, or mixed. ■

INDICATIONS:

- Evaluate type of hearing loss (conductive or sensorineural)
- Screen for hearing loss as part of a routine physical examination and to determine the need for referral to an audiologist

RESULT

Normal Findings:

- Normal air and bone conduction in both ears. No evidence of hearing loss.

- Bing test: Pulsating sound that gets louder and softer when the opening to the ear canal is alternately opened and closed. (*Note:* This result, observed in patients with normal hearing, is also observed in patients with sensorineural hearing loss.)
- Rinne test: Longer and louder tone heard by air conduction than by bone conduction. (*Note:* This result, observed in patients with normal hearing, is also observed in patients with sensorineural hearing loss.)
- Schwabach test: Same tone loudness heard equally long by the examiner and the patient.
- Weber test: Same tone loudness heard equally in both ears.

Abnormal Findings:

- Conduction hearing loss
  Bing test: No change in the loudness of the sound
  Rinne test: Tone louder or detected for a longer time than the air-conducted tone
  Schwabach test: Prolonged duration of tone when compared to that heard by the examiner
  Weber test: Lateralization of tone to one ear indicating loss of hearing on that side (i.e., tone is heard in the poorer ear)
- Sensorineural hearing loss
  Bing test: Pulsating sound that gets louder and softer when the opening to the ear canal is alternately opened and closed
  Rinne test: Tone heard louder by air conduction
  Schwabach test: Shortened duration when compared to that heard by the examiner
  Weber test: Lateralization of tone to one ear indicating loss of hearing on the other side (i.e., tone is heard in the better ear)

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair the results of the examination:

- Poor technique in striking the tuning fork or incorrect placement can result in accurate results.
- Inability of the patient to understand how to identify responses or unwillingness of the patient to cooperate during the test can cause inaccurate results.
- Hearing loss in the examiner can affect results in those tests that utilize hearing comparisons between patient and examiner.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure detects hearing loss.
- Obtain a history of the patient's complaints, including a list of known allergens.
- Obtain a history of the patient's known or suspected hearing loss, including type and cause; ear conditions with treatment regimens; ear surgery; and other tests and procedures to assess and diagnose auditory deficit.
- Obtain a history of results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the table of tests associated with the Auditory System.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that no discomfort will be

experienced during the test. Inform the patient that an audiologist, physician, or nurse performs the test, in a quiet, darkened room, and that to evaluate both ears, the test can take 5 to 10 minutes.

- Ensure that the external auditory canal is clear of impacted cerumen.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Seat the patient in a quiet environment positioned such that the patient is comfortable and is facing the examiner. A tuning fork of 1024 Hz is used because it tests within the range of human speech (400 to 5000 Hz).
- Bing test: Tap the tuning fork handle against the hand to start a light vibration. Hold the handle to the mastoid process behind the ear while alternately opening and closing the ear canal with a finger. Ask the patient to report whether they hear a change in loudness or softness in sound. Record the result as a positive Bing if the patient reports a pulsating change in sound. Record as a negative Bing if no change in loudness is detected.
- Rinne test: Tap the tuning fork handle against the hand to start a light vibration. Have the patient mask the ear not being tested by moving a finger in and out of the ear canal of that ear. Hold the base of the vibrating tuning fork with the thumb and forefinger of the dominant hand and place it in contact with the patient's mastoid process (bone conduction). Ask the patient when the sound is no longer heard. Follow this with placement of the same vibrating tuning fork in front of the ear canal (air conduction) without touching the external part of the ear. Ask the patient which of the two has the loudest or longest tone. Repeat the test in the other ear. Record as Rinne positive if air conduction is heard longer and Rinne negative if bone conduction is heard longer.
- Schwabach test: Tap the tuning fork handle against the hand to start a light vibration. Hold the base of the tuning fork against one side of the patient's mastoid process and ask if the tone is heard. Have the patient mask the ear not being tested by moving a finger in and out of the ear canal of that ear. The examiner then places the tuning fork against the same side of his or her own mastoid process and listens for the tone. The tuning fork is alternated on the same side between patient and examiner until the sound is no longer heard, noting whether the sound ceased to be heard by both the patient and the examiner at the same point in time. Repeat the procedure on the other ear. If the patient hears the tone for a longer or shorter time, count and note this in seconds.
- Weber test: Tap the tuning fork handle against the hand to start a light vibration. Hold the base of the vibrating tuning fork with the thumb and forefinger of the dominant hand and place it on the middle of the patient's forehead or at the vertex of the head. Ask the patient to determine if the sound is heard better and longer on one side than the other. Record as Weber right or left. If sound is heard equally, record as Weber negative.
- The results are recorded manually for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to hearing loss and perceived loss of independence. Dis-

cuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. As appropriate, instruct the patient in the use, cleaning, and storing of a hearing aid. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related dignostic tests:

- Related diagnostic tests include hearing loss audiometry, evoked brain potential studies for hearing loss, otoscopy, and spondee speech reception threshold.

ULTRASOUND, ARTERIAL DOPPLER, CAROTID STUDIES

SYNONYMS/ACRONYM: Carotid Doppler, carotid ultrasound, arterial ultrasound.

AREA OF APPLICATION: Arteries.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Using the duplex scanning method, carotid ultrasound records sound waves to obtain information about the carotid arteries. The amplitude and waveform of the carotid pulse are measured, resulting in a two-dimensional image of the artery. Carotid arterial sites used for the studies include the common carotid, external carotid, and internal carotid. Blood flow direction, velocity, and the presence of flow disturbances can be readily assessed. The sound waves hit the moving red blood cells and are reflected back to the transducer, a flashlight-shaped device, pressed against the skin. The sound that is emitted by the equipment corresponds to the velocity of the blood flow through the vessel. The result is the visualization of the artery to assist in the diagnosis (i.e.,

presence, amount, location) of plaques causing vessel stenosis or atherosclerotic occlusion affecting the flow of blood to the brain. Depending on the degree of stenosis causing a reduction in vessel diameter, additional testing can be performed to determine the effect of stenosis on the hemodynamic status of the artery. ■

INDICATION:

- Assist in the diagnosis of carotid artery occlusive disease, as evidenced by visualization of blood flow disruption
- Detect irregularities in the structure of the carotid arteries
- Detect plaque or stenosis of the carotid artery, as evidenced by turbulent blood flow or changes in Doppler signals indicating occlusion

RESULT

Normal Findings:

- Normal blood flow through the carotid arteries with no evidence of occlusion or narrowing

Abnormal Findings:

- Carotid artery occlusive disease (atherosclerosis)
- Plaque or stenosis of carotid artery
- Reduction in vessel diameter of more than 16%, indicating stenosis

CRITICAL VALUES: N/A

INTERFERING FACTORS

Factors that may impair clear imaging:

- Attenuation of the sound waves by bony structures, which can impair clear imaging of the vessels
- Incorrect placement of the transducer over the desired test site
- Retained contrast medium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the arteries in the neck.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Cardiovascular System table.
- Note any recent procedures that can interfere with test results (i.e., iodine-based contrast or barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium or iodine contrast medium and this test.
- Record the date of the last menstrual

period and determine the possibility of pregnancy in perimenopausal women.

- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination.
- Expose the neck and drape the patient.
- Conductive gel is applied to the skin and a Doppler transducer is moved over the skin to obtain images of the area of interest. When the swishing sound of blood flow is heard, record it at the highest point along the artery at which it is audible.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- When the study is completed, remove the gel from the skin.
- Instruct the patient to continue usual diet, fluids, and medications, as directed by the health care practitioner.
- *Nutritional considerations:* A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information

regarding the clinical implications of the test results, as appropriate.

- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include carotid angiography, computed tomography angiography, and magnetic resonance imaging angiography.

ULTRASOUND, ARTERIAL DOPPLER, LOWER EXTREMITY STUDIES

SYNONYMS/ACRONYM: Doppler, arterial ultrasound, duplex scan.

AREA OF APPLICATION: Arteries of the lower extremities.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Using the duplex scanning method, arterial leg ultrasound records sound waves to obtain information about the arteries of the lower extremities from the common femoral arteries and their branches as they extend into the calf area. The amplitude and waveform of the pulses are measured, resulting in a two-dimensional image of the artery. Blood flow direction, velocity, and the presence of flow disturbances can be readily assessed, and for diagnostic studies, the technique is done bilaterally. The sound waves hit the moving red blood cells and are reflected back to the transducer, a flashlight-shaped device, pressed against the skin. The sound that is emitted by the equip-

ment corresponds to the velocity of the blood flow through the vessel. The result is the visualization of the artery to assist in the diagnosis (i.e., presence, amount, and location) of plaques causing vessel stenosis or occlusion and to help determine the cause of claudication. Arterial reconstruction and graft condition and patency can also be evaluated. ■

INDICATIONS:

- Assist in the diagnosis of aneurysm, pseudoaneurysm, hematoma, arteriovenous malformation, or hemangioma
- Assist in the diagnosis of ischemia, arterial calcification, or plaques, as evidenced by visualization of blood flow disruption
- Detect irregularities in the structure of the arteries
- Detect plaque or stenosis of the lower extremity artery, as evidenced by turbulent blood flow or changes in Doppler signals indicating occlusion

RESULT

Normal Findings:

- Normal blood flow through the lower extremity arteries with no evidence of vessel occlusion or narrowing

Abnormal Findings:

- Aneurysm
- Arterial calcification or plaques
- Graft diameter reduction
- Hemangioma
- Hematoma
- Ischemia
- Pseudoaneurysm
- Reduction in vessel diameter of more than 16%, indicating stenosis
- Vessel occlusion or stenosis

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with an open or draining lesion

Factors that may alter test results:

- Attenuation of the sound waves by bony structures, which can impair clear imaging of the vessels
- Cold extremities, resulting in vasoconstriction that can cause inaccurate measurements
- Occlusion proximal to the site being studied, which would affect blood flow to the area
- Open wound or incision overlying the area to be examined
- Cigarette smoking, because nicotine can cause constriction of the peripheral vessels
- An abnormally large leg, making direct examination difficult
- Incorrect placement of the transducer over the desired test site
- Retained contrast medium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the peripheral arteries.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Cardiovascular System table.
- Report the presence of a lesion that is open or draining; maintain clean, dry dressing for the ulcer; protect the limb from trauma.
- Note any recent procedures that can interfere with test results (i.e., iodine-based contrast or barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium or iodine contrast medium and this test.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.
- *Sensitivity to social and cultural issues*, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure in the area to be examined.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination.
- Expose the area of interest and drape the patient.
- Conductive gel is applied to the skin and a Doppler transducer is moved over the skin to obtain images of the area of interest.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.

- Place blood pressure cuffs on the thigh, calf, and ankle.
- Apply a conductive get to the skin over the area distal to each of the cuffs.
- Inflate the thigh cuff to a level above the patient's systolic pressure found in the normal extremity.
- Place the Doppler transducer on the skin distal to the inflated cuff, and slowly release the pressure in the cuff.
- When the swishing sound of blood flow is heard, record it at the highest point along the artery at which it is audible. The test is repeated at the calf and then the ankle.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- When the study is completed, remove the gel from the skin.
- Instruct the patient to continue usual diet, fluids, and medications, as directed by the health care practitioner
- *Nutritional considerations:* A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography angiography, and magnetic resonance imaging angiography.

ULTRASOUND, A-SCAN

SYNONYMS/ACRONYMS: None.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION & RATIONALE: Diagnostic techniques such as A-scan ultrasonography can be used to identify abnormal tissue. The A-scan employs a single-beam, linear sound wave to detect abnormalities by returning an echo when interference disrupts its straight path. When the sound wave is directed at lens vitreous that is normal, the homogeneous tissue does not return an echo; an opaque lens with a cataract will produce an echo. The returning waves detected by abnormal tissue are received by a microfilm that converts the sound energy into electrical impulses that are amplified and displayed on an oscilloscope as an ultrasonogram or echogram. The A-scan echo can be used to indicate the position of the cornea and retina. The A-scan is most commonly used to measure the axial length of the eye. This measurement is used to determine the power requirement for an intraocular lens used to replace the abnormal, opaque lens of the eye removed in cataract surgery. There are two different methods currently in use. The applanation method involves placement of an ultrasound probe directly on the cornea. The immersion technique is more popular because it does not require direct contact and compression of the cornea. The immersion technique protects the cornea by placement of a fluid layer between the eye and the ultrasound probe. The accuracy of the immersion technique is thought to be greater than that of applanation because there is no corneal compression caused by the immersion method. Therefore, the measured axial length achieved by immersion is closer to the true axial length of the cornea. ■

INDICATIONS:

- Determination of power requirement for replacement intraocular lens in cataract surgery.

RESULT

Normal Findings:

- Normal homogeneous ocular tissue

Abnormal Findings:

- Cataract

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair the results of the examination:

- Inability of the patient to cooperate and remain still during the procedure may interfere with the test results.

- Rubbing or squeezing the eyes may affect results.
- Improper placement of the probe tip to the surface of the eye may produce inaccurate results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure determines the strength of the lens that will be replaced during cataract surgery.
- Obtain a history of the patient's complaints, including a list of known allergens, especially topical anesthetic eyedrops.
- Obtain a history of the patient's known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- Obtain a history of results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the table of tests associated with the Ocular System.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.
- Review the procedure with the patient. Explain that the patient will be requested to fixate the eyes during the procedure. Address concerns about pain related to the procedure. Explain to the patient that no discomfort will be experienced during the test but that some discomfort may be experienced after the test when the numbness wears off from the anesthetic drops administered prior to the test. Inform the patient that a technician, optometrist, or physician performs the test, in a quiet, semi-darkened room, and that evaluation of the eye upon which surgery is to be performed can take up 10 minutes.
- There are no food, fluid or medication restrictions, unless by medical direction.

Intratest:

- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- Seat the patient comfortably. Instruct the patient to look straight ahead, keeping the eyes open and unblinking.
- Instill topical anesthetic in each eye, as ordered, and provide time for it to work. Topical anesthetic drops are placed in the eye with the patient looking up and the solution directed at the six o'clock position of the sclera (white of the eye) near the limbus (grey, semitransparent area of the eyeball where the cornea and sclera meet). The dropper bottle should not touch the eyelashes.
- Ask the patient to place the chin in the chin rest and gently press the forehead against the support bar. When the ultrasound probe is properly positioned on the patient's surgical eye, a reading is automatically taken.
- Multiple measurements may be taken in order to ensure that a consistent and acurate reading has been achieved. Variability between serial measurements is unavoidable using the applanation technique.
- The results are recorded on a paper strip from the automated equipment for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Encourage the patient to recognize and be supportive of impaired activity related to vision loss, perceived loss of driving privileges, or the possibility of requiring corrective lenses (self-image). Discuss the implications of test results on the patient's lifestyle. Reassure the patient regarding concerns related to the impending cataract surgery. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

ULTRASOUND, BLADDER

SYNONYM/ACRONYM: Bladder sonography.

AREA OF APPLICATION: Bladder.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Bladder ultrasound evaluates disorders of the bladder, such as masses or lesions. Bladder position, structure, and size are examined with the use of high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. Methods for imaging include the transrectal, transurethral, and transvaginal approach. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to evaluate the structure and position of the contents of the bladder. The examination is helpful for monitoring patient response to therapy for bladder disease. Bladder images can be included in

ultrasonography of the kidneys, ureters, bladder, urethra, and gonads in diagnosing renal/neurologic disorders. Bladder ultrasound may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures. ■

INDICATIONS:

- Assess residual urine after voiding to diagnose urinary tract obstruction causing overdistention
- Detect tumor of the bladder wall or pelvis, as evidenced by distorted position or changes in bladder contour
- Determine end-stage malignancy of the bladder caused by extension of a primary tumor of the ovary or other pelvic organ
- Evaluate the cause of urinary tract infection, urine retention, and flank pain
- Evaluate hematuria, urinary frequency, dysuria, and suprapubic pain
- Measure urinary bladder volume by transurethral or transvaginal approach

RESULT

Normal Findings:

- Normal size, position, and contour of the bladder

Abnormal Findings:

- Bladder diverticulum
- Cyst
- Cystitis
- Malignancy of the bladder
- Tumor
- Ureterocele
- Urinary tract obstruction

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with latex allergy; use of the vaginal probe requires the probe to be covered with a condom-like sac, usually made from latex. Some covers that are latex-free are available.

Factors that may impair clear imaging:

- Incorrect placement of the transducer over the desired test site
- Retained gas or barium from a previous radiologic procedure
- Patients who are dehydrated, resulting in failure to demonstrate the boundaries between organs and tissue structures
- Insufficiently full bladder, which fails to push the bowel from the pelvis and the uterus from the symphysis pubis, thereby prohibiting clear imaging of the pelvic organs in transabdominal imaging
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined

Other considerations:

- Failure to follow pretesting preparations may cause the procedure to be canceled or repeated.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the bladder and pelvic organs.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the health care practitioner accordingly.
- Obtain a history of the patient's genitourinary, reproductive, and gastrointestinal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Genitourinary, Reproductive, and Gastrointestinal System tables.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium and this test.
- Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography (CT) of the abdomen, if ordered, should be scheduled after this procedure.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.
- For the transvaginal approach, inform the patient that a latex or sterile sheath-covered probe will be inserted into the vagina.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- Inform the patient receiving transabdominal ultrasound that further instruction will be given on the day of the procedure; the procedure requires a full bladder.

Intratest:

- Ensure that the patient has complied with pretesting preparations. Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Instruct the patient receiving transabdominal ultrasound to drink five to six glasses of fluid 90 minutes before the procedure, and not to void before the procedure. Patients receiving transvaginal ultrasound only do not need to have a full bladder.
- Patients are given a gown, robe, and foot coverings to wear.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination. The right- or left-side-up position allows gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- Expose the abdomen area and drape the patient.
- *Transabdominal approach:* Conductive gel is applied to the skin, and a trans-

ducer is moved over the skin while the bladder is distended to obtain images of the area of interest. The sound wave images are projected on the screen and stored electronically or reproduced on film.

- *Transvaginal approach:* A covered and lubricated probe is inserted into the vagina and moved to different levels. Images are obtained and recorded.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.
- If the patient is to be examined for residual urine volume, ask the patient to empty the bladder; repeat the procedure and calculate the volume.

Post-test:

- Allow the patient to void, as needed.
- When the study is completed, remove the gel from the skin.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography scan of the pelvis; cystoscopy; intravenous pyelography; kidney, ureter, and bladder (KUB) study; and magnetic resonance imaging of the pelvis.

ULTRASOUND, BREAST

SYNONYM/ACRONYM: Mammographic ultrasound.

AREA OF APPLICATION: Breast.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. When used in conjunction with mammography and clinical examination, breast ultrasound is indispensable in the diagnosis and management of benign and malignant process. Both breasts are usually examined during this procedure. The examination uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to determine the presence of palpable and nonpalpable masses, their size, and structure. This procedure is useful in patients with an abnormal mass on a mammogram because it can determine whether the abnormality is cystic or solid; that is, it can differentiate between a palpable, fluid-filled cyst and a palpable, solid breast lesion (benign or malignant). It is especially useful in patients with dense breast tissue and in those with silicone prostheses, because the ultrasound beam easily penetrates in these situations, allowing routine examination that cannot be performed with x-ray mammography. The procedure can be done as an adjunct to mammography, or it can be done in place of mammography in patients who refuse having x-ray exposure or those in whom it is contraindicated (e.g., pregnant women, women less than 25 years old). The procedure is indicated as a guide for biopsy or other interventional procedures and as a means of monitoring disease progression or the effects of treatment. ■

INDICATIONS:

- Detect very small tumors in combination with mammography for diagnostic validation
- Determine the presence of nonpalpable abnormalities viewed on mammography of dense breast tissue, and monitor changes in these abnormalities
- Differentiate among types of breast masses (e.g., cyst, solid tumor, other lesions) in dense breast tissue
- Evaluate palpable masses in young (less than age 25), pregnant, and lactating patients
- Guide interventional procedures such as cyst aspiration, large-needle core biopsy, fine-needle aspiration biopsy, abscess drainage, presurgical localization, and galactography
- Identify an abscess in a patient with mastitis

RESULT

Normal Findings:

- Normal subcutaneous, mammary, and retromammary layers of tissue in both breasts; no evidence of pathologic lesions (cyst or tumor) in either breast

Abnormal Findings:

- Abscess
- Breast solid tumor, lesions
- Cancer (ductal carcinoma, infiltrating lobular carcinoma, medullary carcinoma, tubular carcinoma, and papillary carcinoma)
- Cystic breast disease
- Fibroadenoma
- Focal fibrosis
- Galactocele
- Hamartoma (fibroadenolipoma)
- Hematoma
- Papilloma

- Phyllodes tumor
- Radial scar

CRITICAL VALUES: N/A

INTERFERING FACTORS

Factors that may impair clear imaging:

- Incorrect placement of the transducer over the desired test site
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Excessively large breasts
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the breast.
- Obtain a history of the patient's complaints, including a list of known allergens, and inform the health care practitioner accordingly.
- Obtain a history of the patient's reproductive system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Reproductive System table.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient not to apply lotions, bath powder, or other substances to the chest and breast area before the examination.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has not applied lotions, bath powder, or other substances to the chest and breast area before the examination. Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Patients are given a gown and robe to wear.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine posi-

tion on an exam table. The right- and left-side-up positions are also used during the scan to facilitate better organ visualization.

- Expose the breast area and drape the patient.
- Conductive gel is applied to the skin and a transducer is moved over the skin to obtain images of the area of interest. The sound wave images are projected on the screen and stored electronically or reproduced on film.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- When the study is completed, remove the gel from the skin.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include chest x-ray, computed tomography scan of the thorax, and mammogram.

ULTRASOUND, KIDNEY

SYNONYM/ACRONYM: Renal ultrasound, renal sonography.

AREA OF APPLICATION: Kidney.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Renal ultrasound is used to evaluate renal system disorders. It is valuable for determining the internal components of renal masses (solid versus cystic) and for evaluating

other renal diseases, renal parenchyma, perirenal tissues, and obstruction. Ultrasound uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to evaluate the structure, size, and position of the kidney. Renal ultrasound can be performed on the same day as a radionuclide scan or other radiologic procedure, and is especially valuable in patients who are in renal failure, have hypersensitivity to contrast medium, have a kidney that did not visualize on intravenous pyelography (IVP), or are pregnant. It does not rely on renal function or the injection of contrast medium to obtain a diagnosis. The procedure is indicated for evaluation after a kidney transplant and is used as a guide for biopsy or other interventional procedures, abscess drainage, and nephrostomy tube placement. Renal ultrasound may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures. ■

INDICATIONS:

- Aid in the diagnosis of the effect of chronic glomerulonephritis and end-stage chronic renal failure on the kidneys (e.g., decreasing size)
- Detect an accumulation of fluid in the kidney caused by backflow of urine, hemorrhage, or perirenal fluid
- Detect masses and differentiate between cysts or solid tumors, as evidenced by specific waveform patterns or absence of sound waves
- Determine the presence and location of renal or ureteral calculi and obstruction
- Determine the size, shape, and position of a nonfunctioning kidney to identify the cause
- Evaluate or plan therapy for renal tumors
- Evaluate renal transplantation for changes in kidney size
- Locate the site of and guide percutaneous renal biopsy, aspiration needle insertion, or nephrostomy tube insertion
- Monitor kidney development in children when renal disease has been diagnosed
- Provide the location and size of renal masses in patients who are unable to undergo IVP because of poor renal function or an allergy to iodinated contrast medium

RESULT

Normal Findings:

- Absence of calculi, cysts, hydronephrosis, obstruction, or tumor
- Normal size, position, and shape of the kidneys and associated structures

Abnormal Findings:

- Acute glomerulonephritis
- Acute pyelonephritis
- Congenital anomalies, such as absent, horseshoe, ectopic, or duplicated kidney
- Hydronephrosis
- Obstruction of ureters
- Perirenal abscess or hematoma
- Polycystic kidney
- Rejection of renal transplant
- Renal calculi
- Renal cysts, hypertrophy, or tumors
- Ureteral obstruction

CRITICAL VALUES: N/A

INTERFERING FACTORS

Factors that may impair clear imaging:

- Attenuation of the sound waves by the ribs, which can impair clear imaging of the kidney
- Incorrect placement of the transducer over the desired test site
- Retained gas or barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined

Other considerations:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses kidney function.
- Obtain a history of the patient's complaints, including a list of known allergens, and inform the health care practitioner accordingly.
- Obtain a history of the patient's genitourinary system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the genitourinary System table.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium and this test.
- Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography (CT) of the abdomen, if ordered, should be scheduled after this procedure.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Patients are given a gown, robe, and

foot coverings to wear and instructed to void prior to the procedure.

- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination. The right- or left-side-up position allows gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- Expose the abdomen/kidney area and drape the patient.
- Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest. The sound wave images are projected on the screen and stored electronically or reproduced on film.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- When the study is completed, remove the gel from the skin.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include angiography renal, computed tomography scan of the abdomen; intravenous pyelography; kidney, ureter, and bladder (KUB) study; magnetic resonance imaging of the abdomen, and renogram.

ULTRASOUND, LIVER AND BILIARY SYSTEM

SYNONYMS/ACRONYM: Gallbladder ultrasound, liver ultrasound, hepatobiliary sonography.

AREA OF APPLICATION: Liver, gallbladder, bile ducts.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Hepatobiliary ultrasound uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to evaluate the structure, size, and position of the liver and gallbladder in the right upper quadrant (RUQ) of the abdomen. The gallbladder and biliary system collect, store, concentrate, and transport bile to the intestines to aid in digestion. This procedure allows visualization of the gallbladder and bile ducts when the patient may have impaired liver function, and it is especially helpful when done on patients in whom gallstones cannot be visualized with oral or intravenous radiologic studies. Liver ultrasound can be done in combination with a nuclear scan to obtain information about liver function and density differences in the liver. The procedure is indicated as a guide for biopsy or other interventional procedures. Hepatobiliary ultrasound may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures. ■

INDICATIONS:

- Detect cysts, polyps, hematoma, abscesses, hemangioma, adenoma, metastatic disease, hepatitis, or solid tumor of the liver or gallbladder, as evidenced by echoes specific to tissue density and sharply or poorly defined masses
- Detect gallstones or inflammation when oral cholecystography is inconclusive
- Detect hepatic lesions, as evidenced by density differences and echo-pattern changes
- Determine the cause of unexplained hepatomegaly and abnormal liver function tests
- Determine cause of unexplained RUQ pain
- Determine patency and diameter of the hepatic duct for dilation or obstruction

- Differentiate between obstructive and nonobstructive jaundice by determining the cause
- Evaluate response to therapy for tumor, as evidenced by a decrease in size of the organ
- Guide biopsy or tube placement
- Guide catheter placement into the gallbladder for stone dissolution and gallbladder fragmentation

Result

Normal Findings:

- Normal size, position, and shape of the liver and gallbladder, as well as patency of the cystic and common bile ducts

Abnormal Findings:

- Biliary or hepatic duct obstruction/dilation
- Cirrhosis
- Gallbladder inflammation, stones, carcinoma, polyps
- Hematoma or trauma
- Hepatic tumors, metastasis, cysts, hemangioma, hepatitis
- Hepatocellular disease, adenoma
- Hepatomegaly
- Intrahepatic abscess
- Subphrenic abscesses

Critical Values: N/A

Interfering Factors

Factors that may impair clear imaging:

- Attenuation of the sound waves by the ribs, which can impair clear imaging of the right lobe of the liver
- Incorrect placement of the transducer over the desired test site
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:

- Failure to follow dietary restrictions may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the liver and biliary function.
- Obtain a history of the patient's complaints, including a list of known allergens, and inform the health care practitioner accordingly.
- Obtain a history of the patient's hepatobiliary and gastrointestinal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Hepatobiliary and Gastrointestinal System tables.

- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium and this test.
- Endoscopic retrograde cholangiopancreatography (ERCP), colonoscopy, and computed tomography (CT) of the abdomen, if ordered, should be scheduled after this procedure.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- The patient should fast and restrict fluids for 8 hours prior to the procedure.

Intratest:

- Ensure that the patient has complied with dietary and fluids restrictions and pretesting preparations; assure that food and fluids have been restricted for at least 8 hours prior to the procedure. Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination. The right- or left-side-up position allows gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- Expose the abdomen and drape the patient.
- Conductive gel is applied to the skin of the RUQ, and a transducer is moved over the skin to obtain images of the area of interest, including the liver, gallbladder, and bile ducts (cystic and common). The sound wave images are projected on the screen and stored electronically or reproduced on film.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
- Gallbladder contractibility is viewed by scanning after administration of a pharmaceutical that induces gallbladder contraction or after administration of a fatty meal.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- When the study is completed, remove the gel from the skin.
- Instruct the patient to resume usual diet and fluids, as directed by the health care practitioner.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practi-

tioner, who will discuss the results with the patient.

- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include colonoscopy, computed tomography scan of the abdomen, endoscopy, cholangiopancreatography endoscopic retrograde, hepatobiliary scan, and magnetic resonance imaging of the abdomen.

ULTRASOUND, LYMPH NODES AND RETROPERITONEUM

SYNONYM/ACRONYM: Lymph node sonography.

AREA OF APPLICATION: Abdomen, pelvis, and retroperitoneum.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Lymph node ultrasound uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to evaluate the structure, size, and position of the lymph nodes to examine the retroperitoneum and surrounding tissues. This procedure is used for the evaluation of retroperitoneal pathology, usually lymph node enlargement. Ultrasound is the preferred diagnostic method because this area is inaccessible to conventional radiography in diagnosing lymphadenopathy, although it can be used in combination with lymphangiography, magnetic resonance imaging (MRI), and computed tomography (CT) to confirm the diagnosis. The procedure may be used for monitoring the effect of radiation or chemotherapy on the lymph nodes. Lymph node ultrasound may be the diagnostic examination of choice be-

cause no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures. ■

INDICATIONS:

- Detect lymphoma
- Determine the location of enlarged nodes to plan radiation and other therapy
- Determine the size or enlargement of aortic and iliac lymph nodes
- Evaluate the effects of medical, radiation, or surgical therapy on the size of nodes or tumors, as evidenced by shrinkage or continued presence of the mass or nodes

RESULT

Normal Findings:

- Normal retroperitoneal and intrapelvic node size of 1.5 cm in diameter

Abnormal Findings:

- Infection or abscess
- Lymphoma
- Retroperitoneal tumor

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair clear imaging:

- Incorrect placement of the transducer over the desired test site
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Patients who are dehydrated, resulting in failure to demonstrate the boundaries between organs and tissue structures
- Insufficiently full bladder, which fails to push the bowel from the pelvis and the uterus from the symphysis pubis, thereby prohibiting clear imaging of the pelvic organs in transabdominal imaging
- Metallic objects within the examination field (e.g., jewelry, or bodyrings) which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined

Other considerations:

- Failure to follow dietary/fluid instructions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses assesses the lymph nodes and retroperitoneum.
- Obtain a history of the patient's complaints, including a list of known allergens, and inform the health care practitioner accordingly.
- Obtain a history of the patient's genitourinary, reproductive, immune, and gastrointestinal systems, as well as results of previously performed

laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Genitourinary, Reproductive, Immune, and Gastrointestinal System tables.

- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium and this test.
- Endoscopic retrograde cholangiopancreatography (ERCP), colonoscopy, and CT of the abdomen, if ordered, should be scheduled after this procedure.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- The patient should fast and restrict fluids for 8 hours prior to the procedure. Inform the patient that transabdominal ultrasound requires a full bladder.

Intratest:

- Ensure that the patient has complied with dietary and fluids restrictions and pretesting preparations; assure that food and fluids have been restricted for at least 8 hours prior to the procedure. Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Instruct the patient to drink five to six glasses of fluid 90 minutes before the procedure, and not to void before the procedure.
- Patients are given a gown, robe and foot coverings to wear.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination.
- Expose the abdomen area and drape the patient.
- Conductive gel is applied to the skin, and a transducer is moved over the skin while the bladder is distended to obtain images of the area of interest. The sound wave images are projected on the screen and stored electronically or reproduced on film.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Allow the patient to void, as needed.
- When the study is completed, remove the gel from the skin.
- Instruct the patient to resume usual diet and fluids, as directed by the health care practitioner.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practi-

tioner, who will discuss the results with the patient.

- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include angiography of the abdomen; computed tomography scan of the abdomen; kidney, ureter, and bladder (KUB) study; and magnetic resonance imaging of the abdomen.

ULTRASOUND, OBSTETRIC

SYNONYMS/ACRONYM: OB sonography, fetal age sonogram, gestational age sonogram, pregnancy ultrasound, pregnancy echo, pregnant uterus ultrasonography.

AREA OF APPLICATION: Pelvis and abdominal region.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Obstetric ultrasound uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin or inserted into the vagina. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to visualize the fetus and placenta. This procedure is done by a transabdominal or transvaginal approach, depending on when the procedure is performed (first trimester [transvaginal] vs. second trimester [transabdominal]). It is the safest method of examination to evaluate the uterus and determine fetal size, growth, and position; fetal structural abnormalities; ectopic pregnancy; placenta position and amount of amniotic fluid; and multiple gestation. Obstetric ultrasound is used to secure different types of information regarding the fetus, varying with the trimester during which the procedure is done. This procedure can also be used in combination with Doppler

monitoring of the fetal heart or respiratory movements to detect high-risk pregnancy. The procedure is indicated as a guide for amniocentesis, cordocentesis, fetoscopy, aspiration of multiple oocytes for in vitro fertilization, and other intrauterine interventional procedures. Because the pregnant uterus is filled with amniotic fluid, ultrasonography is an ideal method of evaluating the fetus and placenta; it is also the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures. ■

INDICATIONS:

- Detect blighted ovum (missed abortion), as evidenced by empty gestational sac
- Detect fetal death, as evidenced by absence of movement and fetal heart tones
- Detect fetal position before birth, such as breech or transverse presentations
- Detect tubal and other forms of ectopic pregnancy
- Determine and confirm pregnancy or multiple gestation by determining the number of gestational sacs in the first trimester
- Determine cause of bleeding, such as placenta previa or abruptio placentae
- Determine fetal effects of Rh incompatibility
- Determine fetal gestational age by uterine size and measurements of crown-rump length, biparietal diameter, fetal extremities, head, and other parts of the anatomy at key phases of fetal development
- Determine fetal heart and body movements and detect high-risk pregnancy by monitoring fetal heart and respiratory movements in combination with Doppler ultrasound or real-time gray-scale scanning
- Determine fetal structural anomalies, usually at the 20th week of gestation or later
- Determine the placental size, location, and site of implantation
- Differentiate a tumor (hydatidiform mole) from a normal pregnancy
- Guide the needle during amniocentesis and fetal transfusion
- Measure fetal gestational age and evaluate umbilical artery, uterine artery, and fetal aorta by Doppler examination to determine fetal intrauterine growth retardation
- Monitor placental growth and amniotic fluid volume

RESULT

Normal Findings:

- Normal age, size, viability, position, and functional capacities of the fetus
- Normal placenta size, position, and structure; adequate volume of amniotic fluid

Abnormal Findings:

- Abruptio placentae
- Cardiac abnormalities
- Ectopic pregnancy
- Fetal death
- Fetal hydrops
- Fetal malpresentation (breech, transverse)
- Hydrocephalus
- Intestinal atresia
- Myelomeningocele

- Multiple pregnancy
- Placenta previa
- Renal or skeletal defects

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with latex allergy; use of the vaginal probe requires the probe to be covered with a condom-like sac, usually made from latex. Some covers that are latex-free are available.

Factors that may impair clear imaging:

- Incorrect placement of the transducer over the desired test site
- Retained gas or barium from a previous radiologic procedure
- Patients who are dehydrated, resulting in failure to demonstrate the boundaries between organs and tissue structures
- Insufficiently full bladder, which fails to push the bowel from the pelvis and the uterus from the symphysis pubis, thereby prohibiting clear imaging of the pelvic organs in transabdominal imaging
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined

Other considerations:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses abdomen and pelvic organ function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's genitourinary, reproductive, and gastrointestinal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Genitourinary, Reproductive, and Gastrointestinal System tables.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium and this test.
- Endoscopic retrograde cholangiopancreatography, and colonoscopy, if ordered, should be scheduled after this procedure.
- Record the date of the last menstrual period. Obtain a history of menstrual dates, previous pregnancy, and treatment received for high-risk pregnancy.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain

related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.

- For the transvaginal approach, inform the patient that a latex or sterile sheath-covered probe will be inserted into the vagina.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- Inform the patient receiving transabdominal ultrasound that the procedure requires a full bladder.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Instruct the patient receiving transabdominal ultrasound to drink five to six glasses of fluid 90 minutes before the procedure, and not to void before the procedure. Patients receiving transvaginal ultrasound only do not need to have a full bladder.
- Patients are given a gown, robe, and foot coverings to wear.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination. The right- or left-side-up position allows gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- Expose the abdomen area and drape the patient.
- *Transabdominal approach:* Conductive gel is applied to the skin, and a transducer is moved over the skin while the bladder is distended to obtain images of the area of interest. The sound wave images are projected on the screen and stored electronically or reproduced on film.
- *Transvaginal approach:* A covered and lubricated probe is inserted into the vagina and moved to different levels. Images are obtained and recorded.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Allow the patient to void, as needed.
- When the study is completed, remove the gel from the skin.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address

any concerns voiced by the patient or family.

➤ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

➤ Related diagnostic tests include kidney, ureter, and bladder (KUB) study; and magnetic resonance imaging of the abdomen.

ULTRASOUND, PANCREAS

SYNONYM/ACRONYM: Pancreatic ultrasonography.

AREA OF APPLICATION: Pancreas and upper abdomen.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Pancreatic ultrasound uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to determine the size, shape, and position of the pancreas; determine the presence of masses or other abnormalities of the pancreas; and examine the surrounding viscera. The procedure is indicated as a guide for biopsy, aspiration, or other interventional procedures. Pancreatic ultrasound may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures; however, it is usually done in combination with computed tomography (CT) or magnetic resonance imaging (MRI) of the pancreas. ■

INDICATIONS:

- Detect anatomic abnormalities as a consequence of pancreatitis
- Detect pancreatic cancer, as evidenced by a poorly defined mass or a mass in

the head of the pancreas that obstructs the pancreatic duct

- Detect pancreatitis, as evidenced by pancreatic enlargement with increased echoes
- Detect pseudocysts, as evidenced by a well-defined mass with absence of echoes from the interior
- Monitor therapeutic response to tumor treatment
- Provide guidance for percutaneous aspiration and fine-needle biopsy of the pancreas

Result

Normal Findings:

- Normal size, position, contour, and texture of the pancreas

Abnormal Findings:

- Acute pancreatitis
- Calculi
- Pancreatic duct obstruction
- Pancreatic tumor
- Pseudocysts

Critical Values: N/A

Interfering Factors:

Factors that may impair clear imaging:

- Attenuation of the sound waves by the ribs, which can impair clear imaging of the pancreas
- Incorrect placement of the transducer over the desired test site
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined

Other considerations:

- Failure to follow dietary and fluids restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses pancreatic function.
- Obtain a history of the patient's complaints, including a list of known allergens, and inform the health care practitioner accordingly.
- Obtain a history of the patient's endocrine and gastrointestinal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Endocrine and Gastrointestinal System tables.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium and this test.
- Endoscopic retrograde cholangiopancreatography (ERCP), colonoscopy, and CT of the abdomen, if ordered,

should be scheduled after this procedure.

- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- The patient should fast and restrict fluids for 8 hours prior to the procedure.

Intratest:

- Ensure that the patient has complied with dietary and fluids restrictions and pretesting preparations; assure that food and fluids have been restricted for at least 8 hours prior to the procedure. Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination. The right- or left-side-up position allows gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- Expose the abdomen area and drape the patient.
- Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest. The sound wave images are projected on the screen and stored electronically or reproduced on film.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate healthcare practitioner.

Post-test:

- When the study is completed, remove the gel from the skin.
- Instruct the patient to resume usual diet and fluids, as directed by the health care practitioner
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

Related diagnostic tests include CT scan of the abdomen and pancreas; cholangiopancreatography endoscopic retrograde; kidney, ureter, and bladder (KUB) study; and magnetic resonance imaging of the abdomen and pancreas.

ULTRASOUND, PELVIS (GYNECOLOGIC, NONOBSTETRIC)

SYNONYMS/ACRONYM: Pelvic sonography, lower abdomen ultrasound, pelvic gynecologic (GYN) sonogram.

AREA OF APPLICATION: Pelvis and appendix region.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Gynecologic ultrasound uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin or inserted into the vagina. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor in order to:

- Determine the presence, size, and structure of masses and cysts; and determine the position of an intrauterine contraceptive device (IUD)
- Evaluate postmenopausal bleeding
- Examine other abnormalities of the uterus, ovaries, fallopian tubes, and vagina

This procedure is done by a transabdominal or transvaginal approach. The transabdominal approach provides a view of the pelvic organs posterior to the bladder. It requires a full bladder, thereby allowing a window for transmission of the ultrasound waves, pushing the uterus away from the pubic symphysis, pushing the bowel out of the pelvis, and acting as a reference for comparison in the evaluation of the internal structures of a mass or cyst being examined. The transvaginal approach focuses on the female reproductive organs and is often used to monitor ovulation over a period of days in patients undergoing fertility assessment. This approach is also used in obese patients or in

patients with retroversion of the uterus because the sound waves are better able to reach the organ from the vaginal site. Transvaginal images are significantly more accurate compared to anterior transabdominal images in identifying paracervical, endometrial, and ovarian pathology, and the transvaginal approach does not require a full bladder. The procedure is indicated as a guide for biopsy or other interventional procedures. Pelvic ultrasound may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures. ■

INDICATIONS:

- Detect and monitor the treatment of pelvic inflammatory disease (PID) when done in combination with other laboratory tests
- Detect bleeding into the pelvis resulting from trauma to the area or ascites associated with tumor metastasis
- Detect masses in the pelvis and differentiate them from cysts or solid tumors, as evidenced by differences in sound-wave patterns
- Detect pelvic abscess or peritonitis caused by a ruptured appendix or diverticulitis
- Detect pregnancy, including ectopic pregnancy
- Detect the presence of ovarian cysts and malignancy and determine the type, if possible, as evidenced by size, outline, and change in position of other pelvic organs
- Evaluate the effectiveness of tumor therapy, as evidenced by a reduction in mass size
- Evaluate suspected fibroid tumor or bladder tumor
- Evaluate the thickness of the uterine wall
- Monitor placement and location of an IUD
- Monitor follicular size associated with fertility studies or to remove follicles for in vitro transplantation

RESULT

Normal Findings:

- Normal size, position, location, and structure of pelvic organs (e.g., uterus, ovaries, fallopian tubes, vagina); IUD properly positioned within the uterine cavity

Abnormal Findings:

- Endometrioma
- Fibroids (leiomyoma)
- Nonovarian cyst
- Ovarian cysts
- Pelvic abscess
- Peritonitis
- PID
- Uterine tumor or adnexal tumor

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with latex allergy; use of the vaginal probe requires the probe to be covered with a condom-like sac, usually made from latex. Some covers that are latex-free are available.

Factors that may impair clear imaging:

- Incorrect placement of the transducer over the desired test site
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study

- Retained barium from a previous radiologic procedure
- Patients who are dehydrated, resulting in failure to demonstrate the boundaries between organs and tissue structures
- Insufficiently full bladder, which fails to push the bowel from the pelvis and the uterus from the symphysis pubis, thereby prohibiting clear imaging of the pelvic organs in transabdominal imaging
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined

Other considerations:

- Failure to follow dietary/fluid instructions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses pelvic organ function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's genitourinary, reproductive, and gastrointestinal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Genitourinary, Reproductive, and Gastrointestinal System tables.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium and this test.
- Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography (CT) of the abdomen, if ordered, should be scheduled after this procedure.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.
- For the transvaginal approach, inform the patient that a latex or sterile sheath-covered probe will be inserted into the vagina.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.

- The patient should fast and restrict fluids for 8 hours prior to the procedure. Inform the patient receiving transabdominal ultrasound that further instructions will be given on the day of the procedure; the procedure requires a full bladder.

Intratest:

- Ensure that the patient has complied with dietary and fluids restrictions and pretesting preparations; assure that food and fluids have been restricted for at least 8 hours prior to the procedure. Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Instruct the patient receiving transabdominal ultrasound to drink three to five glasses of fluid 90 minutes before the exam, and not to void before the procedure. Patients receiving transvaginal ultrasound do not need to have a full bladder.
- Patients are given a gown, robe, and foot coverings to wear,
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination. The right- or left-side-up position allows gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- Expose the abdomen area and drape the patient.
- *Transabdominal approach:* Conductive gel is applied to the skin, and a transducer is moved over the skin while the bladder is distended to obtain images of the area of interest. The sound wave images are projected on the screen and stored electronically or reproduced on film.
- *Transvaginal approach:* A covered and lubricated probe is inserted into the vagina and moved to different levels. Images are obtained and recorded.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate healthcare practitioner.

Post-test:

- Allow the patient to void, as needed.
- When the study is completed, remove the gel from the skin.
- Instruct the patient to resume usual diet and fluids, as directed by the health care practitioner
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography scan of the abdomen; kidney, ureter, and bladder (KUB) study; and magnetic resonance imaging of the abdomen.

ULTRASOUND, PERIPHERAL DOPPLER

SYNONYMS/ACRONYM: Doppler, venous ultrasound, arterial ultrasound, duplex scan.

AREA OF APPLICATION: Veins and arteries.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Peripheral Doppler ultrasound studies can be used to identify narrowing or occlusions of the veins or arteries. In venous Doppler studies, the Doppler identifies moving red blood cells (RBCs) within the vein. The ultrasound beam is directed at the vein and through the Doppler transducer while the RBCs reflect the beam back to the transducer. The reflected sound waves or echoes can be transformed by a computer into scans, graphs, or audible sounds. Blood flow direction, velocity, and the presence of flow disturbances can be readily assessed. The velocity of the blood flow is transformed as a "swishing" noise, audible through the audio speaker. If the vein is occluded, no swishing sound is heard.

In arterial Doppler studies, arteriosclerotic disease of the peripheral vessels can be detected by slowly deflating blood pressure cuffs that are placed on an extremity such as the calf, ankle, or upper extremity. The systolic pressure of the various arteries of the extremities can be measured. The Doppler transducer can detect the first sign of blood flow through the cuffed artery, even the most minimal blood flow, as evidenced by a swishing noise. There is normally a reduction in systolic blood pressure from the arteries of the arms to the arteries of the legs; a reduction exceeding 20 mm Hg is indicative of occlusive disease (deep vein thrombosis) proximal to the area being tested. This procedure may also be used to monitor the patency of a graft, status of previous corrective surgery, vascular status of the blood flow to a transplanted organ, blood flow to a mass, or the extent of vascular trauma. ■

INDICATIONS:

- Aid in the diagnosis of embolic arterial occlusion
- Aid in the diagnosis of small or large vessel arterial occlusive disease
- Aid in the diagnosis of spastic arterial disease, such as Raynaud's phenomenon
- Aid in the diagnosis of venous occlusion secondary to thrombosis or thrombophlebitis

- Determine the patency of a vascular graft, stent, or previous surgery
- Evaluate the origin of pain related to vascular inflammation
- Evaluate possible arterial trauma

Result

Normal venous findings:

- Normal Doppler venous signal that occurs spontaneously with the patient's respiration
- Normal venous system, with no evidence of occlusion

Normal arterial findings:

- No evidence of arterial occlusion
- Normal arterial systolic and diastolic Doppler signals
- Normal reduction in systolic blood pressure (i.e., less than 20 mm Hg) when compared to a normal extremity
- Normal ankle-to-brachial (AB) arterial blood pressure (ankle pressure divided by brachial pressure; normal AB pressure index is greater than 0.85)

Abnormal venous findings:

- Venous narrowing or occlusion secondary to thrombosis or thrombophlebitis

Abnormal arterial findings:

- AB pressure index less than 0.85, indicating significant arterial occlusive disease within the extremity
- Embolic arterial occlusion
- Large or small vessel arterial occlusive disease
- Spastic arterial occlusive disease, such as Raynaud's phenomenon

Critical Values: N/A

Interfering Factors:

This procedure is contraindicated for:

- Patients with an open or draining lesion

Factors that may alter test results:

- Cigarette smoking, because nicotine can cause constriction of the peripheral vessels
- Attenuation of the sound waves by bony structures, which can impair clear imaging of the vessels
- Incorrect placement of the transducer over the desired test site
- Retained contrast medium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the veins and arteries.
- Obtain a history of the patient's complaints, including a list of known allergens, (especially allergies or sensitivities to latex), and inform the health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related

diagnostic tests, refer to the Cardiovascular System table.

- Report the presence of a lesion that is open or draining; maintain clean, dry dressing for the ulcer; protect the limb from trauma.
- Note any recent procedures that can interfere with test results (i.e., iodine-based contrast or barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium or iodine contrast medium and this test.
- Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography (CT) of the abdomen, if ordered, should be scheduled after this procedure.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination.
- Expose the area of interest and drape the patient.
- Conductive gel is applied to the skin, and a Doppler transducer is moved over the skin to obtain images of the area of interest.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Arterial Doppler studies of the lower extremity:

- Place blood pressure cuffs on the thigh, calf, and ankle.
- Apply a conductive get to the skin over the area distal to each of the cuffs.
- Inflate the thigh proximal cuff to a level above the patient's systolic pressure found in the normal extremity.

- Place the Doppler transducer on the skin distal to the inflated cuff, and slowly release the pressure in the cuff.
- When the swishing sound of blood flow is heard, record it at the highest point along the artery at which it is audible. The test is repeated at the calf and then the ankle.

Post-test:

- When the study is completed, remove the gel from the skin.
- Instruct the patient to continue usual diet, fluids, and medications, as directed by the health care practitioner
- *Nutritional considerations:* A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography angiography, and magnetic resonance imaging angiography.

ULTRASOUND, PROSTATE (TRANSRECTAL)

SYNONYM/ACRONYM: Prostate sonography.

AREA OF APPLICATION: Prostate, seminal vesicles.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Prostate ultrasound is used for the evaluation of disorders of the prostate, especially in response to an elevated concentration of prostate-specific antigen on a blood test and as a complement to a digital rectal examination. It uses high-frequency waves of various intensities delivered by a transducer, a candle-shaped device, which is lubricated, sheathed with a condom, and inserted a few inches into the rectum. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to evaluate the structure, size, and position of the contents of the prostate (e.g., masses), as well as other prostate pathology. It aids in the diagnosis of prostatic cancer by evaluating palpable nodules and is useful as a guide to biopsy. This procedure can evaluate prostate tissue, the seminal vesicles, and surrounding perirectal tissue. It can also be used to stage carcinoma and to assist in radiation seed placement. The examination is helpful in monitoring patient response to therapy for prostatic disease. Micturition disorders can also be evaluated by this procedure. Prostate ultrasound may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures. ■

INDICATIONS:

- Aid in the diagnosis of micturition disorders
- Aid in prostate cancer diagnosis
- Assess prostatic calcifications
- Assist in guided needle biopsy of a suspected tumor
- Assist in radiation seed placement
- Determine prostatic cancer staging
- Detect prostatitis

RESULT

Normal Findings:

- Normal size, consistency, and contour of the prostate gland

Abnormal Findings:

- Benign prostatic hypertrophy or hyperplasia
- Micturition disorders
- Perirectal abscess
- Perirectal tumor
- Prostate abscess
- Prostate cancer
- Prostatitis
- Rectal tumor
- Seminal vesicle tumor

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with latex allergy; use of the rectal probe requires the probe to be covered with a condom, usually made from latex. Some covers that are latex-free are available.

Factors that may impair clear imaging:

- Attenuation of the sound waves by the pelvic bones, which can impair clear imaging of the prostate
- Incorrect placement of the transducer over the desired test site

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined

Other considerations:

- Failure to follow pretesting preparations may cause the procedure to be canceled or repeated.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses prostate.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the health care practitioner accordingly.
- Obtain a history of the patient's genitourinary system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Genitourinary System table.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium and this test.
- Colonoscopy and computed tomography (CT) of the abdomen, if ordered, should be scheduled after this procedure.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.
- Inform the patient that a latex or sterile sheath-covered probe will be inserted into the rectum.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.

Intratest:

- Ensure that the patient has complied with pretesting preparations. Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.

- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient on the examining table on his left side with his knees bent toward the chest; other positions may be used during the examination.
- Expose the pelvic area and drape the patient.
- Cover the rectal probe with a lubricated condom and insert it into the rectum. Inform the patient that he may feel slight pressure as the transducer is inserted. Water may be introduced through the sheath surrounding the transducer. The scan is performed at several levels.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his breath.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- When the study is completed, remove the gel from the skin.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography scan of the pelvis; intravenous pyelography; kidney, ureter, and bladder (KUB) study; magnetic resonance imaging of the pelvis; and renogram.

ULTRASOUND, SCROTAL

SYNONYM/ACRONYM: Scrotal sonography, ultrasound of the testes, testicular ultrasound.

AREA OF APPLICATION: Scrotum.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Scrotal ultrasound is used for the evaluation of disorders of the scrotum. It is valuable in determining the internal components of masses (solid versus cystic) and for the evaluation of the testicle, extratesticular and intrascrotal tissues, benign and malignant tumors, and other scrotal pathology. It uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, which is pressed against the skin. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to evaluate the structure, size, and position of the contents of the scrotum. Scrotal ultrasound can be performed before or after a radionuclide scan for further clarification of a testicular mass. Extratesticular lesions such as hydrocele, hematocele (blood in the scrotum), and pyocele (pus in the scrotum) can be identified, as can cryptorchidism (undescended testicles). Scrotal ultrasound may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures. ■

INDICATIONS:

- Aid in the diagnosis of a chronic inflammatory condition such as epididymitis
- Aid in the diagnosis of a mass and differentiate between a cyst and a solid tumor, as evidenced by specific waveform patterns or the absence of sound waves, respectively
- Aid in the diagnosis of scrotal or testicular size, abnormality, or pathology
- Aid in the diagnosis of testicular torsion and associated testicular infarction
- Assist ultrasound-guided needle biopsy of a suspected testicle tumor
- Determine the cause of chronic scrotal swelling or pain
- Determine the presence of a hydrocele, pyocele, spermatocele, or hernia before surgery
- Evaluate the effectiveness of treatment for testicular infections
- Locate an undescended testicle

RESULT

Normal Findings:

- Normal size, position, and shape of the scrotum and structure of the testes

Abnormal Findings:

- Abscess
- Epididymal cyst
- Epididymitis
- Hematoma
- Hydrocele
- Infarction
- Microlithiasis
- Orchitis
- Pyocele
- Scrotal hernia
- Spermatocele
- Torsion
- Tumor, benign or malignant
- Tunica albuginea cyst
- Undescended testicle (cryptorchidism)
- Varicocele

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair clear imaging:

- Incorrect placement of the transducer over the desired test site
- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the scrotum.
- Obtain a history of the patient's complaints, including a list of known allergens, and inform the health care practitioner accordingly.
- Obtain a history of the patient's genitourinary and reproductive systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Genitourinary and Reproductive System tables.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium and this test.
- Colonoscopy and computed tomography (CT) of the abdomen, if ordered, should be scheduled after this procedure.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Patients are given a gown and robe to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and

follow the general guidelines in Appendix A.

- Place the patient in the supine position on an exam table; other positions may be used during the examination.
- Expose the abdomen/pelvic area and drape the patient.
- Lift the penis upward and gently tape it to the lower part of the abdomen. Elevate the scrotum with a rolled towel or sponge for immobilization. Display particular sensitivity toward the patient regarding any embarrassment he may feel during this part of the procedure.
- Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest. The sound wave images are projected on the screen and stored electronically or reproduced on film.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his breath.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- When the study is completed, remove the gel from the skin.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography scan of the pelvis; kidney, ureter, and bladder (KUB) study; and magnetic resonance imaging of the pelvis.

ULTRASOUND, SPLEEN

SYNONYM/ACRONYM: Spleen ultrasonography.

AREA OF APPLICATION: Spleen/left upper quadrant.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Spleen ultrasound uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to evaluate the structure, size, and position of the spleen. This test is valuable for determining the internal components of splenic masses (solid versus cystic) and evaluating other splenic pathology, splenic trauma, and left upper quadrant perisplenic tissues. It can be performed to supplement a radionuclide scan or computed tomography (CT). It is especially valuable in patients who are in renal failure, are hypersensitive to contrast medium, or are pregnant because it does not rely on adequate renal function or the injection of contrast medium to obtain a diagnosis. The procedure may also be used as a guide for biopsy, other interventional procedures, or abscess drainage. Spleen ultrasound may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures. ■

INDICATIONS:

- Detect the presence of a subphrenic abscess after splenectomy
- Detect splenic masses; differentiate between cysts or solid tumors (in combination with CT), as evidenced by specific waveform patterns or absence of sound waves, respectively; and determine whether they are intrasplenic or extrasplenic
- Determine late-stage sickle cell disease, as evidenced by decreased spleen size and presence of echoes
- Determine the presence of splenomegaly, and assess the size and volume of the spleen in these cases, as evidenced by increased echoes and visibility of the spleen
- Differentiate spleen trauma from blood or fluid accumulation between the splenic capsule and parenchyma
- Evaluate the effect of medical or surgical therapy on the progression or resolution of splenic disease
- Evaluate the extent of abdominal trauma and spleen involvement, including enlargement or rupture, after a recent trauma
- Evaluate the spleen before splenectomy performed for thrombocytopenic purpura

RESULT

Normal Findings:

- Normal size, position, and contour of the spleen and associated structures

Abnormal Findings:

- Abscesses
- Accessory or ectopic spleen
- Infection
- Lymphatic disease, lymph node enlargement
- Splenic calcifications
- Splenic masses, tumors, cysts, or infarction
- Splenic trauma
- Splenomegaly

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair clear imaging:

- Attenuation of the sound waves by the ribs and an aerated left lung, which can impair clear imaging of the spleen
- Masses near the testing site, which can displace the spleen and cause inaccurate results if confused with splenomegaly
- Patients who are dehydrated, resulting in failure to demonstrate the boundaries between organs and tissue structures
- Incorrect placement of the transducer over the desired test site
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined

Other considerations:

- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses splenic function.
- Obtain a history of the patient's complaints, including a list of known allergens, and inform the health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic, immune, and gastrointestinal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Hematopoietic, Immune, and Gastrointestinal System tables.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium and this test.
- Endoscopic retrograde cholangiopancreatography, colonoscopy, and CT of the abdomen, if ordered, should be scheduled after this procedure.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry

(including watches), hairpins, credit cards, and other metallic objects in the area to be examined.

- The patient should fast and restrict fluids for 8 hours prior to the procedure.

Intratest:

- Ensure that the patient has complied with dietary and fluids restrictions and pretesting preparations; assure that food and fluids have been restricted for at least 8 hours prior to the procedure. Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination. The right- or left-side-up position allows gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- Expose the abdomen area and drape the patient.
- Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest. The sound wave images are projected on the screen and stored electronically or reproduced on film.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- When the study is completed, remove the gel from the skin.
- Instruct the patient to resuem usual diet and fluids, as directed by the health care practitioner
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include angiography of the abdomen; computed tomography scan of the abdomen; kidney, ureter, and bladder (KUB) study; and magnetic resonance imaging of the abdomen.

ULTRASOUND, THYROID AND PARATHYROID

SYNONYMS/ACRONYM: Thyroid sonography, parathyroid sonography, thyroid echo.

AREA OF APPLICATION: Thyroid, parathyroid, and anterior neck region.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Thyroid and parathyroid ultrasound uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to determine the position, size, shape, weight, and presence of masses of the thyroid gland; enlargement of the parathyroid glands; and other abnormalities of the thyroid and parathyroid glands and surrounding tissues. The primary purpose of this procedure is to determine whether a nodule is a fluid-filled cyst (usually benign) or a solid tumor (possibly malignant). This procedure is useful in evaluating the glands' response to medical treatment or assessing the remaining tissue after surgical resection. The procedure may be indicated as a guide for biopsy, aspiration, or other interventional procedures. Thyroid and parathyroid ultrasound may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures; it is clearly the procedure of choice when examining the glands of pregnant patients. This procedure is usually done in combination with nuclear medicine imaging procedures and computed tomography (CT) of the neck. Despite the advantages of the procedure, in some cases it may not detect small nodules and lesions (less than 1 cm), leading to false-negative findings. ■

INDICATIONS:

- Assist in determining the presence of a tumor, as evidenced by an irregular border and shadowing at the distal edge, peripheral echoes, or high- and low-amplitude echoes, depending on the density of the tumor mass; and diagnosing tumor type (e.g., benign, adenoma, carcinoma)
- Assist in diagnosing the presence of a cyst, as evidenced by a smoothly outlined, echo-free amplitude except at the far borders of the mass

- Assist in diagnosis in the presence of a parathyroid enlargement indicating a tumor or hyperplasia, as evidenced by an echo pattern of lower amplitude than that for a thyroid tumor
- Determine the need for surgical biopsy of a tumor or fine-needle biopsy of a cyst
- Differentiate among a nodule, solid tumor, or fluid-filled cyst
- Evaluate the effect of a therapeutic regimen for a thyroid mass or Graves' disease by determining the size and weight of the gland
- Evaluate thyroid abnormalities during pregnancy

Result

Normal Findings:

- Normal size, position, contour, and structure of the thyroid and parathyroid glands with uniform echo patterns throughout the glands; no evidence of tumor cysts or nodules in the glands

Abnormal Findings:

- Glandular enlargement
- Goiter
- Graves' disease
- Parathyroid tumor or hyperplasia
- Thyroid cysts
- Thyroid tumors (benign or malignant)

Critical Values: N/A

Interfering Factors

Factors that may impair clear imaging:

- Attenuation of the sound waves by the ribs, which can impair clear imaging of the parathyroid
- Incorrect placement of the transducer over the desired test site
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined

Other considerations:

- Nodules less than 1 cm in diameter may not be detected.
- Nonthyroid cysts may appear the same as thyroid cysts.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses thyroid and parathyroid function.
- Obtain a history of the patient's complaints, including a list of known allergens, and inform the health care practitioner accordingly.
- Obtain a history of the patient's endocrine system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Endocrine System table.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium and this test.

- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination.
- Expose the neck and chest area and drape the patient.
- Hyperextend the neck, and place a pillow under the patient's shoulders to maintain a comfortable position. (An alternative method of imaging includes the use of a bag filled with water or gel placed over the neck area; the bag serves as a transmitter of the waves from the transducer to the thyroid.)
- Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest. The sound wave images are projected on the screen and stored electronically or reproduced on film.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- When the study is completed, remove the gel from the skin.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include chest x-ray, computed tomography of the thorax, magnetic resonance imaging of the chest, and thyroid scan.

ULTRASOUND, VENOUS DOPPLER, EXTREMITY STUDIES

SYNONYMS/ACRONYM: Venous ultrasound, venous sonogram, venous ultrasonography, venous duplex.

AREA OF APPLICATION: Veins of the upper and lower extremities.

CONTRAST: Done without contrast.

DESCRIPTION & RATIONALE: Ultrasound procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Venous Doppler ultrasound records sound waves to obtain information about the patency of the venous vasculature in the upper and lower extremities. Ultrasound waves are sent into the body by a small transducer pressed against the body. The transducer sends the sound waves into the body and also receives the returning sound waves, which are deflected back as they bounce off various structures. The transducer converts and amplifies the returning sound waves into electrical signals that are transformed by a computer into audible sounds, graphic readings, and gray-scale images. Blood flow direction and velocity can be readily assessed; and the presence of blood flow disturbances, which are proportional to blood flow velocity, can be determined.

For diagnostic studies, the procedure is done bilaterally. The sound waves hit the moving red blood cells and are reflected back to the transducer. The sound emitted by the equipment corresponds to the velocity of the blood flow through the vessel occurring with spontaneous respirations. Changes in these sounds during respirations indicate the possibility of abnormal venous flow secondary to occlusive disease; the absence of sound indicates complete obstruction. Compression with a transducer augments a vessel for evaluation of thrombosis. Noncompressibility of the vessel indicates a thrombosis. Plethysmography may be performed to determine the filling time of calf veins to diagnose thrombotic disorder of a major vein and to identify incompetent valves in the venous system. An additional method used to evaluate incompetent valves is the Valsalva technique combined with venous duplex imaging. ■

INDICATIONS:

- Aid in the diagnosis of superficial thrombosis or deep vein thrombosis (DVT) leading to venous occlusion or obstruction, as evidenced by absence of

venous flow, especially upon augmentation of the extremity; variations in flow during respirations; or failure of the veins to compress completely when the extremity is compressed

- Detect chronic venous insufficiency, as evidenced by reverse blood flow indicating incompetent valves
- Determine if further diagnostic procedures are needed to make or confirm a diagnosis
- Determine the source of emboli when pulmonary embolism is suspected or diagnosed
- Determine venous damage after trauma to the site
- Differentiate between primary and secondary varicose veins
- Evaluate the patency of the venous system in patients with a swollen, painful leg
- Monitor the effectiveness of therapeutic interventions

Result

Normal Findings:

- Normal blood flow through the veins of the extremities with no evidence of vessel occlusion

Abnormal Findings:

- Chronic venous insufficiency
- Primary varicose veins
- Recannulization in the area of an old thrombus
- Secondary varicose veins
- Superficial thrombosis or DVT
- Venous occlusion
- Venous trauma

Critical Values: N/A

Interfering Factors:

This procedure is contraindicated for:

- Patients with an open or draining lesion

Factors that may alter test results:

- Cigarette smoking, because nicotine can cause constriction of the peripheral vessels
- Attenuation of the sound waves by bony structures, which can impair clear imaging of the vessels
- Incorrect placement of the transducer over the desired test site
- Retained contrast medium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the ultrasound equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Cold extremities, resulting in vasoconstriction that can cause inaccurate measurements
- Occlusion proximal to the site being studied, which would affect blood flow to the area
- An abnormally large or swollen leg, making sonic penetration difficult
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the veins and arteries.
- Obtain a history of the patient's complaints, including a list of known allergens, and inform the health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Cardiovascular System table.
- Report the presence of a lesion that is open or draining; maintain clean, dry dressing for the ulcer; protect the limb from trauma.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium or iodine contrast medium and this test.
- Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography (CT) of the abdomen, if ordered, should be scheduled after this procedure.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a ultrasound department, usually by a technologist, and takes approximately 30 to 60 minutes.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination.
- Expose the area of interest and drape the patient.
- Conductive gel is applied to the skin, and a transducer is moved over the area to obtain images of the area of interest. Waveforms are visualized and recorded with variations in respirations. Images with and without compression are performed proximally or distally to an obstruction to

obtain information about a venous occlusion or obstruction. The procedure can be performed for both arms and legs to obtain bilateral blood flow determination.

- Do not place the transducer on an ulcer site when there is evidence of venous stasis or ulcer.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- When the study is completed, remove the gel from the skin.
- Instruct the patient to continue usual diet, fluids, and medications, as directed by the health care practitioner
- *Nutritional considerations:* A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography angiography, and magnetic resonance imaging angiography.

UPPER GASTROINTESTINAL AND SMALL BOWEL SERIES

SYNONYMS/ACRONYMS: Stomach series, gastric radiography, small bowel study, upper GI series, UGI.

AREA OF APPLICATION: Esophagus, stomach, and small intestine.

CONTRAST: Barium sulfate.

DESCRIPTION & RATIONALE: The upper gastrointestinal (GI) series is a radiologic examination of the esophagus, stomach, and small intestine after ingestion of barium sulfate, which is a milkshake-like, radiopaque substance. A combination of x-ray and fluoroscopy techniques is used to record the study. Air may be instilled to provide double contrast and better visualization of the lumen of the esophagus, stomach, and duodenum. If perforation or obstruction is suspected, a water-soluble iodinated contrast medium is used. This test is especially useful in the evaluation of patients experiencing dysphagia, regurgitation, gastroesophageal reflux (GER), epigastric pain, hematemesis, melena, and unexplained weight loss. This test is also used to evaluate the results of gastric surgery, especially when an anastomotic leak is suspected. When a small bowel series is included, the test detects disorders of the jejunum and ileum. The patient's position is changed during the examination to allow visualization of the various structures and their function. The images are visualized on a fluoroscopic screen, recorded, and stored electronically or on x-ray film for review by a physician. Drugs such as glucagon may be given during an upper GI series to relax the GI tract; drugs such as metoclopramide (Reglan) may be given to accelerate the passage of the barium through the stomach and small intestine.

When the small bowel series is performed separately, the patient may be asked to drink several glasses of barium or enteroclysis may be used to instill the barium. With enteroclysis, a catheter is passed through the nose or mouth and advanced past the pylorus and into the duodenum. Barium, followed by methylcellulose solution, is instilled via the catheter directly into the small bowel. ■

INDICATIONS:

- Determine the cause of regurgitation or epigastric pain
- Determine the presence of neoplasms, ulcers, diverticula, obstruction, foreign body, and hiatal hernia
- Evaluate suspected GER, inflammatory

process, congenital anomaly, motility disorder, or structural change

- Evaluate unexplained weight loss or anemia
- Identify and locate the origin of hematemesis

Result

Normal Findings:

- Normal size, shape, position, and functioning of the esophagus, stomach, and small bowel

Abnormal Findings:

- Achalasia
- Cancer of the esophagus
- Chalasis
- Congenital abnormalities
- Duodenal cancer, diverticula, and ulcers
- Esophageal diverticula, motility disorders, ulcers, varices, and inflammation
- Gastric cancer, tumors, and ulcers
- Gastritis
- Hiatal hernia
- Perforation of the esophagus, stomach, or small bowel
- Polyps
- Small bowel tumors
- Strictures

Critical Values: N/A

Interfering Factors

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
- Patients with an intestinal obstruction
- Patients suspected of having upper GI perforation, in whom barium should not be used

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and poor-quality study
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images

Other considerations:

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Patients with swallowing problems may aspirate the barium, which could interfere with the procedure and cause patient complications.
- Possible constipation or partial bowel obstruction caused by retained barium in the small bowel or colon may affect test results.
- This procedure should be done after a kidney x-ray (intravenous pyelography) or computed tomography (CT) of the abdomen or pelvis.
- Risks associated with radiographic overexposure can result from frequent

x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the upper GI system and/or small bowel.
- Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, and dyes.
- Obtain a history of the patient's gastrointestinal system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Gastrointestinal System table.
- Ensure that this procedure is performed before a barium swallow.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Explain the purpose of the test and how the procedure is performed. Inform the patient that the procedure is performed in a radiology department, usually by a health care practitioner and support staff, and takes approximately 30 to 60 minutes.
- Explain to the patient that he or she will be asked to drink a milkshake-like solution that has a chalky taste.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.
- The patient should fast and refrain from drinking liquids for 8 hours prior to the procedure.

Intratest:

- Ensure that the patient has complied with dietary restrictions and pretesting preparations for at least 8 hours prior to the procedure. Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Have emergency equipment readily available.
- Remove any wires connected to electrodes, if allowed.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.

Upper gastrointestinal series:

- Place the patient on the x-ray table in a supine position, or ask the patient to stand in front of an x-ray fluoroscopy screen.
- Instruct the patient to take several swallows of the barium mixture through a straw while images are taken of the pharyngeal motion. Drinking through a straw allows some air to be introduced into the abdomen. This permits detailed examination of the stomach's lining. This same effect can be achieved by administering an effervescent agent.

- While the patient continues to drink the barium solution, images of the esophageal area are recorded from a variety of angles.
- Instruct the patient to finish the barium mixture while images are taken at different angles and positions to aid in the evaluation of stomach filling and emptying into the duodenum.

Small bowel series:

- If the small bowel is to be examined after the upper GI series, instruct the patient to drink an additional glass of barium while the small intestine is observed for passage of barium. Images are taken at 30- to 60-minute intervals until the barium reaches the ileocecal valve. This process can last up to 5 hours, with a follow-up film taken at 24 hours.

General:

- The results are recorded manually, on x-ray film, or by automated equipment in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet and fluids, as directed by the health care practitioner.
- Monitor for reaction to iodinated contrast medium, including including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting, if iodine is used.
- Instruct the patient to take a mild laxative and increase fluid intake (four glasses) to aid in the elimination of barium, unless contraindicated.
- Inform the patient that his or her stool will be white or light in color for 2 to 3 days. If the patient is unable to eliminate the barium, or if the stool does not return to normal color, the patient should notify the health care practitioner.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the abdomen; endoscopic retrograde cholangiopancreatography; kidney, ureter, and bladder (KUB) study; and magnetic resonance imaging of the abdomen.

UREA NITROGEN, BLOOD

SYNONYM/ACRONYM: BUN.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 0.357)
Newborn–3 y	5–17 mg/dL	1.8–6.0 mmol/L
4–13 y	7–17 mg/dL	2.5–6.0 mmol/L
14 y–adult	8–21 mg/dL	2.9–7.5 mmol/L
Adult older than 90 y	10–31 mg/dL	3.6–11.1 mmol/L

DESCRIPTION & RATIONALE: Urea is a nonprotein nitrogen compound formed in the liver from ammonia as an end product of protein metabolism. Urea diffuses freely into extracellular and intracellular fluid and is ultimately excreted by the kidneys. Blood urea nitrogen (BUN) levels reflect the balance between the production and excretion of urea. BUN and creatinine values are commonly evaluated together. The normal BUN/creatinine ratio is 15:1 to 24:1. (e.g., if a patient has a BUN of 15 mg/dL, the creatinine should be approximately 0.6 to 1.0 mg/dL). BUN is used in the following calculation to estimate serum osmolality: ■

$$[(2[Na^+])+(\text{glucose}/18)+(\text{BUN}/2.8)]$$

INDICATIONS:

- Assess nutritional support
- Evaluate hemodialysis therapy
- Evaluate hydration
- Evaluate liver function
- Evaluate patients with lymphoma after chemotherapy (tumor lysis)
- Evaluate renal function
- Monitor the effects of drugs known to be nephrotoxic or hepatotoxic

RESULT

Increased in:

- Acute renal failure
- Chronic glomerulonephritis
- Congestive heart failure
- Decreased renal perfusion

- Diabetes
- Excessive protein ingestion
- Gastrointestinal (GI) bleeding (excessive blood protein in the GI tract)
- Hyperalimentation
- Hypovolemia
- Ketoacidosis
- Muscle wasting from starvation
- Neoplasms
- Nephrotoxic agents
- Pyelonephritis
- Shock
- Urinary tract obstruction

Decreased in:

- Inadequate dietary protein
- Low-protein/high-carbohydrate diet
- Malabsorption syndromes
- Pregnancy
- Severe liver disease

CRITICAL VALUES:

Greater than 100 mg/dL (nondialysis patients)

Note and immediately report to the health care practitioner any critically increased or decreased values and related symptoms. A patient with a grossly elevated BUN may have signs and symptoms including acidemia, agitation, confusion, fatigue, nausea, vomiting, and coma. Possible interventions include treatment of the cause, administration of intravenous bicarbonate, a low-protein diet, hemodialysis, and caution with respect to prescribing and continuing nephrotoxic medications.

INTERFERING FACTORS:

- Drugs, substances, and vitamins that may increase BUN levels include acetaminophen, alanine, aldatense, alkaline antacids, amphotericin B, antimony compounds, arsenicals, bacitracin, bismuth subsalicylate, capreomycin, carbenoxolone, carbutamide, cephalosporins, chloral hydrate, chloramphenicol, chlorthalidone, colistimethate, colistin, cotrimoxazole, dexamethasone, dextran, diclofenac, doxycycline, ethylene glycol, gentamicin, guanethidine, guanoxan, ibuprofen, ifosfamide, ipodate, kanamycin, mephenesin, metolazone, mitomycin, neomycin, phosphorus, plicamycin, tertatolol, tetracycline, triamterene, triethylenemelamine, viomycin, and vitamin D.
- Drugs that may decrease BUN levels include acetohydroxamic acid, chloramphenicol, fluorides, paramethasone, phenothiazine, and streptomycin.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assess renal function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's genitourinary system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Genitourinary System table.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient is regularly using these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately

5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.

- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Monitor intake and output for fluid imbalance in renal dysfunction and dehydration.
- *Nutritional considerations:* Nitrogen balance is commonly used as a nutritional assessment tool to indicate protein change. In healthy individuals, protein anabolism and catabolism are in equilibrium. During various disease states, nutritional intake decreases, resulting in a negative balance. During recovery from illness and with proper nutritional support, the nitrogen balance becomes positive. BUN is an important analyte to measure during administration of total parenteral nutrition (TPN). Educate the patient, as appropriate, in dietary adjustments required to maintain proper nitrogen balance. Inform the patient that the requesting health care practitioner may prescribe TPN as part of the treatment plan.
- *Nutritional considerations:* An elevated BUN can be caused by a high-protein diet or dehydration. Unless medically restricted, a healthy diet consisting of the five food groups of the food pyramid should be consumed daily. Water consumption should include six to eight 8-ounce glasses of water per day, or water consumption equivalent to half of the body's weight in ounces.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in

relation to the patient's symptoms and other tests performed.

Related laboratory tests:

Related laboratory tests include anion gap, blood and urine creatinine, BUN/creatinine ratio, creatinine clearance, blood and urine electrolytes, gentamicin, kidney stone analysis, microalbumin, blood and urine osmolality, tobramycin, urine urea nitrogen, blood and urine uric acid, and vancomycin.

UREA NITROGEN, URINE

SYNONYM/ACRONYM: N/A.

SPECIMEN: Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

REFERENCE VALUE: (Method: Spectrophotometry)

Conventional Units	SI Units (Conventional Units × 35.7)
12–20 g/24 h	428–714 mmol/24 h

DESCRIPTION & RATIONALE: Urea is a nonprotein nitrogen compound formed in the liver from ammonia as an end product of protein metabolism. Urea diffuses freely into extracellular and intracellular fluid and is ultimately excreted by the kidneys. Urine urea nitrogen levels reflect the balance between the production and excretion of urea. ■

INDICATIONS:

- Evaluate renal disease
- Predict the impact that other conditions, such as diabetes and liver disease, will have on the kidneys

RESULT

Increased in:

- Diabetes
- Hyperthyroidism
- Increased dietary protein
- Postoperative period

Decreased in:

- Liver disease
- Low-protein/high-carbohydrate diet
- Normal-growing pediatric patients
- Pregnancy
- Renal disease
- Toxemia

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase urine urea nitrogen levels include alanine and glycine.
- Drugs that may decrease urine urea nitrogen levels include furosemide, growth hormone, insulin, and testosterone.
- All urine voided for the timed collection period must be included in the collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assess renal function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's genitourinary and hepatobiliary systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Genitourinary and Hepatobiliary System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
- Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

Random specimen (collect in early morning):

Clean-catch specimen:

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse

the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.

- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling catheter:

- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 minutes before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Timed specimen:

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container's label the amount of urine, test start and stop times, and ingestion of any medications that can affect test results.

General:

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- *Nutritional considerations:* An elevated BUN can be caused by a high-protein diet or dehydration. Unless medically restricted, a healthy diet consisting of the five food groups of the food pyramid should be consumed daily. Water consumption should include six to eight 8-ounce glasses of water per day, or water consumption equivalent to half of the body's weight in ounces.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change

in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include anion gap, blood urea nitrogen (BUN)/creatinine ratio, blood and urine creatinine, creatinine clearance, blood and urine electrolytes, gentamicin, kidney stone analysis, microalbumin, BUN, blood and urine osmolality, tobramycin, blood and urine uric acid, urinalysis, and vancomycin.

URETHROGRAPHY, RETROGRADE

SYNONYM/ACRONYM: N/A.

AREA OF APPLICATION: Urethra.

CONTRAST: Radiopaque contrast medium.

DESCRIPTION & RATIONALE: Retrograde urethrography is performed almost exclusively in male patients. It uses contrast medium, either injected or instilled via a catheter into the urethra, to visualize the membranous, bulbar, and penile portions, particularly after surgical repair of the urethra to assess the success of the surgery. The posterior portion of the urethra is visualized better when the procedure is performed with voiding cystourethrography. In women, it may be performed after surgical repair of the urethra to assess the success of the surgery and to assess structural abnormalities in conjunction with an evaluation for voiding dysfunction. ■

INDICATIONS: Aid in the diagnosis of urethral strictures, lacerations, diverticula, and congenital anomalies

RESULT

Normal Findings:

- Normal size, shape, and course of the membranous, bulbar, and penile portions of the urethra in male patients
- If the prostatic portion can be visualized, it also should appear normal

Abnormal Findings:

- Congenital anomalies, such as urethral valves and perineal hypospadias
- False passages in the urethra
- Prostatic enlargement
- Tumors of the urethra
- Urethral calculi
- Urethral diverticula
- Urethral fistulas
- Urethral strictures and lacerations

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images

Other considerations:

- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the urethra.
- Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, and dyes.
- Obtain a history of the patient's gastrointestinal and genitourinary systems results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Gastrointestinal and Genitourinary System tables.
- Ensure that this procedure is performed before an upper gastrointestinal study or barium swallow.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Explain the purpose of the test and how the procedure is performed.

Inform the patient that the procedure is performed in a cystoscopy room by a urologist and takes approximately 30 minutes.

- If the contrast medium is instilled through a catheter, inform the patient that some pressure may be experienced when the catheter is inserted and contrast medium is instilled.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry (including watches), credit cards, keys, coins, cell phones, pagers, and other metallic objects.
- Patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hours after the test. Failure to do so may result in lactic acidosis.
- There are no food or fluid restrictions, unless by medical direction.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

Intratest:

- Ensure that the patient has complied with medication restrictions and pretesting preparations. Ensure that the patient has removed all external metallic objects (jewelry, etc.) from the abdominal area prior to the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to lie still during the procedure because movement produces unclear images.
- Obtain and record the patient's baseline vital signs.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient on the table in a supine position in the recumbent position.
- A single plain film is taken of the bladder and urethra.
- A catheter is filled with contrast medium to eliminate air pockets and is inserted until the balloon reaches the meatus. Inform the patient that the contrast medium may cause a temporary flushing of the face, a feeling of warmth, urticaria, headache, vomiting, or nausea.
- The patient is placed in the right posterior oblique position with the thigh drawn up to a 90° angle; in male patients, the penis is placed parallel to the leg.
- After three-fourths of the contrast medium is injected, another exposure is taken while the remainder of the contrast medium is injected.
- Left lateral and oblique exposures may be taken.
- The procedure may be done on female patients using a double balloon to occlude the bladder neck from above and below the external meatus.
- Wear gloves during the radionuclide administration and while handling the patient's urine.
- The results are recorded manually, on x-ray film, or by automated equipment in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Monitor vital and neurologic signs every 15 minutes until they return to preprocedure levels.
- Instruct the patient to resume usual diet and medications, as directed by the physician. Renal function should be assessed before metformin is restarted.
- Monitor fluid intake and urinary output for 24 hours after the procedure. Decreased urine output may indicate impending renal failure.

- Monitor for signs and symptoms of sepsis, including fever, chills, and severe pain in the kidney area.
- Maintain the patient on adequate hydration after the procedure. Encourage the patient to drink lots of fluids to prevent stasis and to prevent the buildup of bacteria.
- Advise patient to drink increased amounts of fluids for 24 to 48 hours to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hours.
- Instruct the patient to immediately flush the toilet after each voiding after the procedure, and to meticulously wash hands with soap and water after each voiding for 24 hours after the procedure.
- Tell all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash ungloved hands after the gloves are removed.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the abdomen, cystoscopy, intravenous pyelography, magnetic resonance imaging of the abdomen, renogram, and renal ultrasound.

URIC ACID, BLOOD

SYNONYM/ACRONYM: Urate.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 0.059)
Child less than 12 y	2.0–5.5 mg/dL	0.12–0.32 mmol/L
Adult younger than 60 y		
Male	4.4–7.6 mg/dL	0.26–0.45 mmol/L
Female	2.3–6.6 mg/dL	0.14–0.39 mmol/L
Adult older than 60 y		
Male	4.2–8.0 mg/dL	0.25–0.48 mmol/L
Female	3.5–7.3 mg/dL	0.21–0.43 mmol/L

DESCRIPTION & RATIONALE: Uric acid is the end product of purine metabolism. Purines are important constituents of nucleic acids; purine turnover occurs continuously in the body, producing substantial amounts of uric acid even in the absence of purine intake from dietary sources such as organ meats (e.g., liver, thymus gland and/or pancreas [sweetbreads], kidney), legumes, and yeasts. Uric acid is filtered, absorbed, and secreted by the kidneys and is a common constituent of urine. Serum urate levels are affected by the amount of uric acid produced and by the efficiency of renal excretion. ■

INDICATIONS:

- Assist in the diagnosis of gout when there is a family history (autosomal dominant genetic disorder) or signs and symptoms of gout, indicated by elevated uric acid levels
- Determine the cause of known or suspected renal calculi
- Evaluate the extent of tissue destruction in infection, starvation, excessive exercise, malignancies, chemotherapy, or radiation therapy
- Evaluate possible liver damage in eclampsia, indicated by elevated uric acid levels
- Monitor the effects of drugs known to alter uric acid levels, either as a side effect or as a therapeutic effect

RESULT

Increased in:

- Acute tissue destruction as a result of starvation or excessive exercise
- Alcoholism
- Chemotherapy and radiation therapy
- Chronic lead toxicity
- Congestive heart failure
- Diabetes
- Down syndrome
- Eclampsia
- Excessive dietary purines
- Glucose-6-phosphate dehydrogenase deficiency
- Gout
- Hyperparathyroidism
- Hypertension
- Hypoparathyroidism
- Lactic acidosis
- Lead poisoning
- Lesch-Nyhan syndrome
- Multiple myeloma
- Pernicious anemia
- Polycystic kidney disease

- Polycythemia
- Psoriasis
- Sickle cell anemia
- Type III hyperlipidemia

Decreased in:

- Fanconi's syndrome
- Low-purine diet
- Severe liver disease
- Wilson's disease

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs and substances that may increase uric acid levels include acetylsalicylic acid (low doses), aldatense, aminothiadiazole, anabolic steroids, antineoplastic agents, ascorbic acid, chlorambucil, chlorthalidone, cisplatin, corn oil, cyclosporine, cyclothiazide, cytarabine, diapamide, diazoxide, diuretics, ergothioneine, ethacrynic acid, ethambutol, ethoxzolamide, etoposide, flumethiazide, hydroflumethiazide, hydroxyurea, ibufenac, ibuprofen, levarterenol, levodopa, mefruside, mercaptopurine, methicillin, methotrexate, methoxyflurane, methyclothiazide, mitomycin, morinamide, polythiazide, prednisone, pyrazinamide, salicylate, spironolactone, theophylline, thiazide diuretics, thioguanine, thiotepa, thiouric acid, triamterene, trichlormethiazide, vincristine, warfarin, and xylitol.
- Drugs that may decrease uric acid levels include acetohexamide, allopurinol, aspirin (high doses), azathioprine, benzbromaron, benziodarone, canola oil, chlorothiazide (given intravenously), chlorpromazine, chlorprothixene, cinchophen, corticosteroids, corticotropin, clofibrate, coumarin, diatrizoic acid, dicumarol, dipyrone, enalapril, fenofibrate, flufenamic acid, guaifenesin, hydralazine, iodipamide, iodopyracet, iopanoic acid, ipodate, lisinopril, mefenamic acid, mersalyl, methotrexate, oxyphenbutazone, phenindione, phenolsulfonphthalein, probenecid, seclazone, sulfinpyrazone, and verapamil.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to diagnose gout and to evaluate renal function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly. Especially note pain and edema in joints and great toe (caused by precipitation of sodium urates), headache, fatigue, decreased urinary output, and hypertension.
- Obtain a history of the patient's genitourinary, hepatobiliary, and musculoskeletal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Genitourinary, Hepatobiliary, and Musculoskeletal System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient is regularly using these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to cultural and social issues*, as well as concern for mod-

esty, is important in providing psychological support before, during, and after the procedure.

- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Increased uric acid levels may be associated with the formation of kidney stones. Educate the patient, if appropriate, on the importance of drinking a sufficient amount of water when kidney stones are suspected.
- *Nutritional considerations:* Increased uric acid levels may be associated with gout. Nutritional therapy may be appropriate for some patients identified as having gout. Educate the patient that foods high in oxalic acid include caffeinated beverages, raw blackberries, gooseberries and plums, whole-wheat bread, beets, carrots, beans, rhubarb, spinach, dry cocoa, and Ovaltine. Foods high in purines include organ meats. In other cases, the requesting health care practitioner may not prescribe a low-purine or purine-restricted diet for treatment of gout because medications can control the condition easily and effectively.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include complete blood count, creatinine, creatinine clearance, kidney stone analysis, synovial fluid analysis, and urine uric acid.

URIC ACID, URINE

SYNONYM/ACRONYM: Urine urate.

SPECIMEN: Urine (5 mL) from a random or timed specimen collected in a clean plastic, unrefrigerated collection container. Sodium hydroxide preservative may be recommended to prevent precipitation of urates.

REFERENCE VALUE: (Method: Spectrophotometry)

Gender	Conventional Units*	SI Units (Conventional Units × 0.0059)*
Male	250–800 mg/24 h	1.48–4.72 mmol/24 h
Female	250–750 mg/24 h	1.48–4.43 mmol/24 h

*Values reflect average purine diet.

DESCRIPTION & RATIONALE: Uric acid is the end product of purine metabolism. Purines are important constituents of nucleic acids; purine turnover occurs continuously in the body, producing substantial amounts of uric acid even in the absence of purine intake from dietary sources such as organ meats (e.g., liver, thymus gland and/or pancreas [sweetbreads], kidney), legumes, and yeasts. Uric acid is filtered, absorbed, and secreted by the kidneys and is a common constituent of urine. ■

INDICATIONS:

- Compare urine and serum uric acid levels to provide an index of renal function
- Detect enzyme deficiencies and metabolic disturbances that affect the body's production of uric acid
- Monitor the response to therapy with uricosuric drugs
- Monitor urinary effects of disorders that cause hyperuricemia

RESULT

Increased in:

- Disorders associated with impaired renal tubular absorption, such as Fanconi's syndrome and Wilson's disease
- Disorders of purine metabolism
- Excessive dietary intake of purines
- Gout
- Neoplastic disorders, such as leukemia, lymphosarcoma, and multiple myeloma
- Pernicious anemia
- Polycythemia vera
- Sickle cell anemia

Decreased in:

- Folic acid deficiency
- Lead toxicity

- Severe renal damage (possibly resulting from chronic glomerulonephritis, collagen disorders, diabetic glomerulosclerosis, lactic acidosis, ketoacidosis, and alcohol abuse)

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase urine uric acid levels include acetaminophen, acetohexamide, ampicillin, ascorbic acid, azapropazone, benzbromarone, chlorpromazine, chlorprothixene, corticotropin, coumarin, cytotoxics, diatrizoic acid, dicumarol, ethyl biscoumacetate, glycine, iodipamide, iodopyracet, iopanoic acid, ipodate, levodopa, mannose, merbarone, mercaptopurine, mersalyl, methotrexate, niacinamide, phenindione, phenolsulfonphthalein, phenylbutazone, phloridzin, probenecid, salicylates (long-term, large doses), seclazone, sulfinpyrazone, theophylline, verapamil, and xylitol.
- Drugs that may decrease urine uric acid levels include acetylsalicylic acid (small doses), allopurinol, ascorbic acid, azathioprine, benzbromaron, bumetanide, chlorothiazide, chlorthalidone, citrates, ethacrynic acid, ethambutol, ethoxzolamide, hydrochlorothiazide, levarterenol, niacin, pyrazinoic acid, and thiazide diuretics.
- All urine voided for the timed collection period must be included in the collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to identify overexcretors at risk of calculus formation, identify genetic defects, and assist in monitoring therapy for gout.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's genitourinary system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Genitourinary System table.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
- Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- *Sensitivity to social and cultural issues,* as well as concern for

modesty, is important in providing psychological support before, during, and after the procedure.

- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

Random specimen (collect in early morning):

Clean-catch specimen:

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling catheter:

- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 minutes before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Timed specimen:

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container's label the amount of urine, test start and stop times, and any medications that can affect test results.

General:

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Increased uric acid levels may be associated with the formation of kidney stones. Educate the patient, if appropriate, on the importance of

drinking a sufficient amount of water when kidney stones are suspected.

- *Nutritional considerations:* Increased uric acid levels may be associated with gout. Nutritional therapy may be appropriate for some patients identified as having gout. Educate the patient that foods high in oxalic acid include caffeinated beverages, raw blackberries, gooseberries and plums, whole-wheat bread, beets, carrots, beans, rhubarb, spinach, dry cocoa, and Ovaltine. Foods high in purines include organ meats. In other cases, the requesting health care practitioner may not prescribe a low-purine or purine-restricted diet for treatment of gout because medications can control the condition easily and effectively.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include urine calcium, complete blood count, urine creatinine, kidney stone analysis, urine oxalate, blood uric acid, and urinalysis.

URINALYSIS

SYNONYM/ACRONYM: UA.

SPECIMEN: Urine (15 mL) from an unpreserved, random specimen collected in a clean plastic collection container.

REFERENCE VALUE: (Method: Macroscopic evaluation by dipstick and microscopic examination) Urinalysis comprises a battery of tests including a description of the color and appearance of urine; measurement of specific gravity and pH; and semiquantitative measurement of protein, glucose, ketones, urobilinogen, bilirubin, hemoglobin, nitrites, and leukocyte esterase. Urine sediment may also be examined for the presence of crystals, casts, renal epithelial cells, transitional epithelial cells, squamous epithelial cells, white blood cells (WBCs), red blood cells (RBCs), bacteria, yeast,

sperm, and any other substances excreted in the urine that may have clinical significance. Examination of urine sediment is performed microscopically under high power, and results are reported as the number seen per high-power field (hpf). The color of normal urine ranges from light yellow to deep amber. The color depends on the patient's state of hydration (more concentrated samples are darker in color), diet, medication regimen, and exposure to other substances that may contribute to unusual color or odor. The appearance of normal urine is clear. Cloudiness is sometimes attributable to the presence of amorphous phosphates or urates as well as blood, WBCs, fat, or bacteria. Normal specific gravity is 1.001 to 1.035.

Dipstick

pH	5.0–9.0
Protein	Less than 20 mg/dL
Glucose	Negative
Ketones	Negative
Hemoglobin	Negative
Bilirubin	Negative
Urobilinogen	Up to 1 mg/dL
Nitrite	Negative
Leukocyte esterase	Negative

Microscopic Examination

Red blood cells	Less than 5/hpf
White blood cells	Less than 5/hpf
Renal cells	None seen
Transitional cells	None seen
Squamous cells	Rare; usually no clinical significance
Casts	Rare hyaline; otherwise, none seen
Crystals in acid urine	Uric acid, calcium oxalate, amorphous urates
Crystals in alkaline urine	Triple phosphate, calcium phosphate, ammonium biurate, calcium carbonate, amorphous phosphates
Bacteria, yeast, parasites	None seen

DESCRIPTION & RATIONALE: Routine urinalysis, one of the most widely ordered laboratory procedures, is used for basic screening purposes. It is a group of tests that evaluate the kidneys' ability to selectively excrete and reabsorb substances while maintaining proper water balance. The results can provide valuable information regarding the overall health of the patient and the patient's response to disease and treatment. The urine dipstick has a number of pads on it to indicate various biochemical markers. Urine pH is an indication of the kidneys' ability to help maintain balanced hydrogen ion

concentration in the blood. Specific gravity is a reflection of the concentration ability of the kidneys. Urine protein is the most common indicator of renal disease, although there are conditions that can cause benign proteinuria. Glucose is used as an indicator of diabetes. The presence of ketones indicates impaired carbohydrate metabolism. Hemoglobin indicates the presence of blood, which is associated with renal disease. Bilirubin is used to assist in the detection of liver disorders. Urobilinogen indicates hepatic or hematopoietic conditions. Nitrites and leukocytes are used to test for bacteriuria and other sources of urinary tract infections (UTIs). Most laboratories have established criteria for the microscopic examination of urine based on patient population (e.g., pediatric, oncology, urology), unusual appearance, and biochemical reactions. ■

INDICATIONS:

- Determine the presence of a genitourinary infection or abnormality
- Monitor the effects of physical or emotional stress
- Monitor fluid imbalances or treatment for fluid imbalances
- Monitor the response to drug therapy and evaluate undesired reactions to drugs that may impair renal function
- Provide screening as part of a general physical examination, especially on admission to a health care facility or before surgery

RESULT

Unusual Color

Color	Presence of
Deep yellow	Riboflavin
Orange	Bilirubin, chrysophanic acid, pyridium, santonin
Pink	Beet pigment, hemoglobin, myoglobin, porphyrin, rhubarb
Red	Beet pigment, hemoglobin, myoglobin, porphyrin,uroerythrin
Green	Oxidized bilirubin, Clorets (breath mint)
Blue	Diagnex, indican, methylene blue
Brown	Bilirubin, hematin, methemoglobin, metronidazole, nitrofurantoin, metabolites of rhubarb, senna
Black	Homogentisic acid, melanin
Smokey	Red blood cells

Test	Increased in	Decreased in
pH	Ingestion of citrus fruits Metabolic and respiratory alkalosis Vegetarian diets	High-protein diets Ingestion of fruits (e.g.,cranberries) Metabolic or respiratory acidosis

(*Continued on the following page*)

Test	Increased in	Decreased in
Protein	Benign proteinuria owing to stress, physical exercise, exposure to cold, or standing Diabetic nephropathy Glomerulonephritis Nephrosis Toxemia of pregnancy	N/A
Glucose	Diabetes	N/A
Ketones	Diabetes Fasting Fever High-protein diets Isopropanol intoxication Postanesthesia period Starvation Vomiting	N/A
Hemoglobin	Diseases of the bladder Exercise (march hemoglobinuria) Glomerulonephritis Hemolytic anemia or other causes of hemolysis (e.g., drugs, parasites, transfusion reaction) Malignancy Menstruation Paroxysmal cold hemoglobinuria Paroxysmal nocturnal hemoglobinuria Pyelonephritis Snake or spider bites Trauma Tuberculosis Urinary tract infections Urolithiasis	N/A
Urobilinogen	Cirrhosis Heart failure Hemolytic anemia Hepatitis Infectious mononucleosis Malaria Pernicious anemia	Antibiotic therapy (suppresses normal intestinal flora) Obstruction of the bile duct
Bilirubin	Cirrhosis Hepatic tumor Hepatitis	N/A

Test	Increased in	Decreased in
Nitrites	Presence of nitrite-forming bacteria (e.g., *Citrobacter, Enterobacter, Escherichia coli, Klebsiella, Proteus, Pseudomonas, Salmonella,* and some species of *Staphylococcus*)	N/A
Leukocyte esterase	Bacterial infection Calculus formation Fungal or parasitic infection Glomerulonephritis Interstitial nephritis Tumor	N/A

Formed Elements in Urine Sediment

Cellular elements:

- Clue cells (cell wall of the bacteria causes adhesion to epithelial cells) are present in nonspecific vaginitis caused by *Gardnerella vaginitis, Mobiluncus cortisii,* and *Mobiluncus mulieris.*
- RBCs are present in glomerulonephritis, lupus nephritis, focal glomerulonephritis, calculus, malignancy, infection, tuberculosis, infarction, renal vein thrombosis, trauma, hydronephrosis, polycystic kidney, urinary tract disease, prostatitis, pyelonephritis, appendicitis, salpingitis, diverticulitis, gout, scurvy, subacute bacterial endocarditis, infectious mononucleosis, hemoglobinopathies, coagulation disorders, heart failure, and malaria.
- Renal cells that have absorbed cholesterol and triglycerides are also known as *oval fat bodies.*
- Renal cells come from the lining of the collecting ducts, and increased numbers indicate acute tubular damage as seen in acute tubular necrosis, pyelonephritis, malignant nephrosclerosis, acute glomerulonephritis, acute drug or substance (salicylate, lead, or ethylene glycol) intoxication, or chemotherapy, resulting in desquamation, urolithiasis, and kidney transplant rejection.
- Squamous cells line the vagina and distal portion of the urethra. The presence of normal squamous epithelial cells in female urine is generally of no clinical significance. Abnormal cells with enlarged nuclei indicate the need for cytologic studies to rule out malignancy.
- Transitional cells line the renal pelvis, ureter, bladder, and proximal portion of the urethra. Increased numbers are seen with infection, trauma, and malignancy.
- WBCs are present in acute UTI, tubulointerstitial nephritis, lupus nephritis, pyelonephritis, kidney transplant rejection, fever, and strenuous exercise.

Casts:

- Granular casts are formed from protein or by the decomposition of cellular elements. They may be seen in renal disease, viral infections, or lead intoxication.
- Large numbers of hyaline casts may be seen in renal diseases, hypertension, congestive heart failure, or nephrotic syndrome, and in more benign condi-

tions such as fever, exposure to cold temperatures, exercise, or diuretic use.

- RBC casts may be found in acute glomerulonephritis, lupus nephritis, and subacute bacterial endocarditis.
- Waxy casts are seen in chronic renal failure or conditions such as kidney transplant rejection, in which there is renal stasis.
- WBC casts may be seen in lupus nephritis, acute glomerulonephritis, interstitial nephritis, and acute pyelonephritis.

Crystals:

- Crystals found in freshly voided urine have more clinical significance than crystals seen in a urine sample that has been standing for more than 2 to 4 hours.
- Calcium oxalate crystals are found in ethylene glycol poisoning, urolithiasis, high dietary intake of oxalates, and Crohn's disease.
- Cystine crystals are seen in patients with cystinosis or cystinuria.
- Leucine or tyrosine crystals may be seen in patients with severe liver disease.
- Large numbers of uric acid crystals are seen in patients with urolithiasis, gout, high dietary intake of foods rich in purines, or receiving chemotherapy (see monograph titled "Uric Acid, Urine").

CRITICAL VALUES:

Possible critical values are the presence of uric acid, cystine, leucine, or tyrosine crystals.

The combination of grossly elevated urine glucose and ketones is also considered significant.

Note and immediately report to the health care practitioner any critical values and related symptoms.

INTERFERING FACTORS:

- Certain foods, such as onion, garlic, and asparagus, contain substances that may give urine an unusual odor. An ammonia-like odor may be produced by the presence of bacteria. Urine with a maple syrup–like odor may indicate a congenital metabolic defect (maple syrup urine disease).
- The various biochemical strips are subject to interference that may produce false-positive or false-negative results. Consult the laboratory for specific information regarding limitations of the method in use and a listing of interfering drugs.
- The dipstick method for protein detection is mostly sensitive to the presence of albumin; light-chain or Bence Jones proteins may not be detected by this method. Alkaline pH may produce false-positive protein results.
- Large amounts of ketones or ascorbic acid may produce false-negative or decreased color development on the glucose pad. Contamination of the collection container or specimen with chlorine, sodium hypochlorite, or peroxide may cause false-positive glucose results.
- False-positive ketone results may be produced in the presence of ascorbic acid, levodopa metabolites, valproic acid, phenazopyridine, phenylketones, or phthaleins.
- The hemoglobin pad may detect myoglobin, intact RBCs, and free hemoglobin. Contamination of the collection container or specimen with sodium hypochlorite or iodine may cause false-positive hemoglobin results. Negative or decreased hemoglobin results may occur in the presence of formalin, elevated protein, nitrite, ascorbic acid, or high specific gravity.
- False-negative nitrite results are common. Negative or decreased results may be seen in the presence of ascorbic acid and high specific gravity. Other causes of false-negative values relate to the amount of time the urine was in the

bladder before voiding or the presence of pathogenic organisms that do not reduce nitrates to nitrites.

- False-positive leukocyte esterase reactions result from specimens contaminated by vaginal secretions. The presence of high glucose, protein, or ascorbic acid concentrations may cause false-negative results. Specimens with high specific gravity may also produce false-negative results. Patients with neutropenia (e.g., oncology patients) may also have false-negative results because they do not produce enough WBCs to exceed the sensitivity of the biochemical reaction.
- Specimens that cannot be delivered to the laboratory or tested within 1 hour should be refrigerated or should have a preservative added that is recommended by the laboratory. Specimens collected more than 2 hours before submission may be rejected for analysis.
- Because changes in the urine specimen occur over time, prompt and proper specimen processing, storage, and analysis are important to achieve accurate results. Changes that may occur over time include:
  - Production of a stronger odor and an increase in pH (bacteria in the urine break urea down to ammonia)
  - A decrease in clarity (as bacterial growth proceeds or precipitates form)
  - A decrease in bilirubin and urobilinogen (oxidation to biliverdin and urobilin)
  - A decrease in ketones (lost through volatilization)
  - Decreased glucose (consumed by bacteria)
  - An increase in bacteria (growth over time)
  - Disintegration of casts, WBCs, and RBCs
  - An increase in nitrite (overgrowth of bacteria)

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the diagnosis of renal disease, urinary tract infections, and neoplasms of the urinary tract, and as an indication of systemic or inflammatory diseases.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine, genitourinary, immune, hematopoietic, hepatobiliary, and reproductive systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine, Genitourinary, Immune, Hematopoietic, Hepatobiliary, and Reproductive System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient is regularly using these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. If a catheterized specimen is to be collected, explain this procedure to the patient, and obtain a catheterization tray. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure. Inform the patient that specimen collection takes approximately 5 to 10 minutes.
- *Sensitivity to social and cultural issues*, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medica-

tion restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

Random specimen (collect in early morning):

Clean-catch specimen:

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Pediatric urine collector:

- Put on gloves. Appropriately cleanse the genital area, and allow the area to dry. Remove the covering over the adhesive strips on the collector bag, and apply the bag over the genital area. Diaper the child. When specimen is obtained, place the entire collection bag in a sterile urine container.

Indwelling catheter:

- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 minutes before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Urinary catheterization:

- Place female patient in lithotomy position or male patient in supine position. Using sterile technique, open the straight urinary catheterization kit and perform urinary catheterization. Place the retained urine in a sterile specimen container.

Suprapubic aspiration:

- Place the patient in a supine position. Cleanse the area with antiseptic and drape with sterile drapes. A needle is inserted through the skin into the bladder. A syringe attached to the needle is used to aspirate the urine sample. The needle is then removed and a sterile dressing is applied to the site. Place the sterile sample in a sterile specimen container.
- Do not collect urine from the pouch from the patient with a urinary diversion (e.g., ilieal conduit). Instead, perform catheterization through the stoma.

General:

- Include on the collection container's label whether the specimen is clean catch or catheter and any medications that may interfere with test results.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to report symptoms such as pain related to tissue inflammation, pain or irritation during void, bladder spasms, or alterations in urinary elimination.

- Observe for signs of inflammation if the specimen is obtained by suprapubic aspiration.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Instruct the patient with a UTI, as appropriate, on the proper technique for wiping the perineal area (front to back) after a bowel movement. UTIs are more common in women who use diaphragm/spermicide contraception. These patients can be educated, as appropriate, in the proper insertion and removal of the contraceptive device to avoid recurrent UTIs.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Instruct the patient to begin antibiotic therapy, as prescribed, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if symptoms are no longer present. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include blood and urine amino acids, anti–glomerular basement membrane antibody, bladder biopsy, kidney biopsy, bladder cancer marker, urine calcium, complete blood count, blood and urine creatinine, relevant cultures, blood and urine electrolytes, glucose, glycated hemoglobin, blood and urine ketones, kidney stone analysis, microalbumin, urine osmolality, urine oxalate, urine protein, blood and urine protein immunofixation electrophoresis, urine phosphorus, blood and urine urea nitrogen, and blood and urine uric acid.

UTERINE FIBROID EMBOLIZATION

SYNONYMS/ACRONYM: UFE.

AREA OF APPLICATION: Uterus.

CONTRAST: Intravenous iodine based.

DESCRIPTION & RATIONALE: Uterine fibroid embolization (UFE) is a way of treating fibroid tumors of the uterus. Fibroid tumors, also known as myomas, are masses of fibrous and muscle tissue in the uterine wall that

are benign, but that may cause heavy menstrual bleeding, pain in the pelvic region, or pressure on the bladder or bowel. A catheter is placed in each of the two uterine arteries, and small particles are injected to block the arterial branches that supply blood to the fibroids. The fibroid tissue dies, the mass shrinks, and the symptons are relieved. This procedure, which is done under local anesthesia, is less invasive than open surgery done to remove uterine fibroids. Because the effects of uterine fibroid embolization on fertility are not yet known, the ideal candidate is a premenopausal woman with symptoms from fibroid tumors who no longer wishes to become pregnant. This technique is an alternative for women who do not want to receive blood transfusions or do not wish to receive general anesthesia. This procedure may be used to halt severe bleeding following childbirth or caused by gynecologic tumors. ■

INDICATIONS:

- Treatment for anemia from chronic blood loss
- Treatment of fibroid tumors and tumor vascularity, for both single and multiple tumors
- Treatment of tumors in lieu of surgical resection

RESULT

Normal Findings:

- Decrease in uterine bleeding
- Decrease of pelvic pain or fullness

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients with bleeding disorders.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Patients in whom cancer is a possibility or who have inflammation or infection in the pelvis.
- Elderly and other patients who are chronically dehydrated before the procedure, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.

Factors that may impair clear imaging:

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings, dental amalgams), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined

Other considerations:

- Complications of the procedure include hemorrhage, infection at the insertion site, and cardiac arrhythmias.

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.
- A small percent of women may pass a small piece of fibroid tissue after the procedure. Women with this problem may require a procedure called a D&C (dilatation and curettage).
- Some women may experience menopause shortly after the procedure.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses uterine and associated vascular function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, and dyes), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular and reproductive systems, as well as results of previously performed laboratory tests (especially coagulation tests, blood urea nitrogen, and creatinine, if contrast medium is to be used), surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Cardiovascular and Reproductive System tables.
- Note any recent procedures that can interfere with test results; include examinations utilizing barium or iodine-based contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain that a sedative and/or anesthetic may be administered before the procedure to promote relaxation. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a radiology or vascular department by a health care practitioner and support staff and takes approximately 30 to 120 minutes.
- Explain that an intravenous (IV) line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- Inform the patient that a burning and flushing sensation may be felt

throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.

- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- The patient should fast and restrict fluids for 8 hours prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.
- Patients receiving metformin (glucophage) for non–insulin dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hours after the test. Failure to do so may result in lactic acidosis.
- Instruct the patient to remove, jewelry (including watches), hairpins, credit cards, and other metallic objects from the area being examined.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*
- This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.

Intratest:

- Ensure that the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations; assure that these have been restricted for at least 8 hours prior to the procedure. Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs and assess neurologic status. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to an uncooperative adult, as ordered.
- Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.
- Using a pen, mark the site of the patient's peripheral pulses before angiography; this allows for quicker and more consistent assessment of the pulses after the procedure.
- Place the patient in the supine position on an exam table. Cleanse the selected area, and cover with a sterile drape.
- A local anesthetic is injected at the site, and a small incision is made or a needle inserted. The femoral artery or vein is punctured, and the guidewire inserted. The catheter is inserted over the guidewire and threaded into the uterine artery under fluoroscopy.
- The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to examine the vessels

after a time and to monitor the venous phase of the procedure.

- Ask the patient to inhale deeply and hold her breath while the x-ray images are taken, and then to exhale after the images are taken.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- Particles are injected through the catheter to block the blood flow to the fibroids. The particles include polyvinyl alcohol, gelatin sponge (Gelfoam), and micospheres.
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The results are recorded on x-ray film or electronically, in a computerized system, for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the health care practitioner. Renal function should be assessed before metformin is resumed.
- Monitor vital signs and neurologic status every 15 minutes for 1 hour, then every 2 hours for 4 hours, and then as ordered by the health care practitioner. Take temperature every 4 hours for 24 hours. Compare with baseline values. Notify the health care practitioner if temperature is elevated. Protocols may vary from facility to facility.
- Patients may experience plevic cramps for several days after the procedure and possible mild nausea and fever.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting,
- Advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation. Note any pleuritic pain, persistent right shoulder pain, or abdominal pain.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema. Instruct the patient in the care and assessment of the site.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to genitourinary system. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage her to review correspon-

ding literature provided by a pharmacist.

- It may take 2 to 3 months for the fibroids to shrink so that bulk-related symptoms such as pain and pressure improve. Heavy bleeding may improve during the first menstrual cycle following the procedure.
- Most women are able to return to work 1 to 2 weeks after the procedure.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography angiography, computed tomography of the plevis, magnetic resonance angiography, magnetic resonance imaging of the pelvis, and ultrasound of the pelvis.

VANILLYLMANDELIC ACID, URINE

SYNONYM/ACRONYM: VMA.

SPECIMEN: Urine (25 mL) from a timed specimen collected in a clean plastic collection container with 6N hydrochloric acid as a preservative.

REFERENCE VALUE: (Method: High-pressure liquid chromatography)

Age	Conventional Units	SI Units (Conventional Units × 5.05)
3–6 y	1.0–2.6 mg/24 h	5–13 μmol/24 h
6–10 y	2.0–3.2 mg/24 h	10–16 μmol/24 h
10–16 y	2.3–5.2 mg/24 h	12–26 μmol/24 h
16–83 y	1.4–6.5 mg/24 h	7–33 μmol/24 h

DESCRIPTION & RATIONALE: Vanillylmandelic acid (VMA) is a major metabolite of epinephrine and norepinephrine. It is elevated in conditions that also are marked by overproduction of catecholamines. Creatinine is usually measured simultaneously to ensure adequate collection and to calculate an excretion ratio of metabolite to creatinine. ■

INDICATIONS:

- Assist in the diagnosis of neuroblastoma, ganglioneuroma, or pheochromocytoma
- Evaluate hypertension of unknown cause

RESULT

Increased in:

- Ganglioneuroma
- Hypertension
- Neuroblastoma
- Pheochromocytoma

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase VMA levels include ajmaline, chlorpromazine, glucagon, guaifenesin, guanethidine, isoproterenol, methyldopa, nitroglycerin, oxytetracycline, phenazopyridine, phenolsulfonphthalein, prochlorperazine, rauwolfia, reserpine, sulfobromophthalein, and syrosingopine.
- Drugs that may decrease VMA levels include brofaromine, guanethidine, guanfacine, imipramine, isocarboxazid, methyldopa, monoamine oxidase inhibitors, morphine, nialamide (in schizophrenics), and reserpine.
- Stress, hypoglycemia, hyperthyroidism, strenuous exercise, smoking, and drugs can produce elevated catecholamines.
- Recent radioactive scans within 1 week of the test can interfere with test results.
- Failure to collect all urine and store 24-hour specimen properly will result in a falsely low result.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the diagnosis and follow-up treatment of pheochromocytoma, neuroblastoma, and ganglioblastoma. It is also useful in evaluation and follow-up of hypertension.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's endocrine system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Endocrine System table.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
- Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.

- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- *Sensitivity to social and cultural issues*, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no fluid restrictions unless by medical direction.
- Instruct the patient to abstain from smoking tobacco for 24 hours before testing.
- Inform the patient of the following dietary, medication, and activity restrictions in preparation for the test:
  - The patient should not consume foods high in amines for 48 hours before testing (bananas, avocados, beer, aged cheese, chocolate, cocoa, coffee, fava beans, grains, tea, vanilla, walnuts, and red wine).
  - The patient should not consume foods or fluids high in caffeine for 48 hours before testing (coffee, tea, cocoa, and chocolate).
  - The patient should not consume any foods or fluids containing vanilla or licorice.
  - The patient should avoid self-prescribed medications (especially aspirin) and prescribed medications (especially pyridoxine, levodopa, amoxicillin, carbidopa, reserpine, and disulfiram) for 2 weeks before testing and as directed.
  - The patient should avoid excessive exercise and stress during the 24-hour collection of urine.

Intratest:

- Ensure that the patient has complied with dietary, medication, and activity restrictions and pretesting preparations prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

Timed specimen:

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container's label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.

- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the health care practitioner.
- *Nutritional considerations:* Instruct the patient to avoid foods or drinks containing caffeine. Over-the-counter medications should be taken only under the advice of the patient's health care practitioner.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include catecholamines, homovanillic acid, and metanephrines.

VARICELLA ANTIBODIES

SYNONYMS/ACRONYM: Varicella zoster antibodies, chickenpox, VZ.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Indirect fluorescent antibody) Negative or less than a fourfold increase in titer.

DESCRIPTION & RATIONALE: Varicella-zoster is a double-stranded DNA herpesvirus that is responsible for two clinical syndromes, chickenpox and shingles. The incubation period is 2 to 3 weeks, and it is highly contagious for about 2 weeks beginning 2 days before a rash develops. It is

transmitted in respiratory secretions. The primary exposure to the highly contagious virus usually occurs in susceptible school-age children. Adults without prior exposure and who become infected may have severe complications, including pneumonia. Neonatal infection from the mother is possible if exposure occurs during the last 3 weeks of gestation. Shingles results when the presumably latent virus is reactivated. The presence of immunoglobulin (Ig) M antibodies indicates acute infection. The presence of IgG antibodies indicates current or past infection. A reactive varicella antibody result indicates immunity but does not protect an individual from shingles. There are also polymerase chain reaction methods that are capable of detecting varicella-zoster DNA in various specimen types. ■

INDICATIONS: Determine susceptibility or immunity to chickenpox

RESULT

Positive findings in: Varicella infection

Negative findings in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to confirm diagnosis of varicella infection or immunity.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of exposure to varicella.
- Obtain a history of the patient's immune and reproductive systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Immune and Reproductive System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient is regularly using these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm diagnosis. Any individual positive result should be repeated in 7 to 14 days to monitor a change in titer. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in

Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.

- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Vaccination considerations:* Record the date of last menstrual period and determine the possibility of pregnancy prior to administration of varicella vaccine to female varicella-nonimmune patients. Instruct patient not to become pregnant for 1 month after being vaccinated with the varicella vaccine to protect any fetus from contracting the disease and having serious birth defects. Instruct on birth control methods to prevent pregnancy, if appropriate.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and provide emotional support if results are positive and the patient is pregnant. Inform the patient with shingles regarding access to pain management. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Instruct the patient in isolation precautions during the time of communicability or contagion. Emphasize the need to return to have a convalescent blood sample taken in 7 to 14 days. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

VENOGRAPHY, LOWER EXTREMITY STUDIES

SYNONYMS/ACRONYM: Phlebography, lower limb venography, venogram.

AREA OF APPLICATION: Veins of the lower extremities.

CONTRAST: Intravenous iodine based.

DESCRIPTION & RATIONALE: Venography allows x-ray visualization of the venous vasculature system of the extremities after injection of an iodinated contrast medium. Lower extremity studies identify and locate thrombi within the venous system of the lower limbs. After injection of the contrast medium, x-ray films are taken at timed intervals. Usually both extremities are studied, and the unaffected side is used for comparison with the side suspected of having deep vein thrombosis (DVT) or other venous abnormalities, such as congenital malformations or incompetent valves. Thrombus formation usually occurs in the deep calf veins and at the venous junction and its valves. If DVT is not treated, it can lead to femoral and iliac venous occlusion, or the thrombus can become an embolus, causing a pulmonary embolism. Venography is accurate for thrombi in veins below the knee. ■

INDICATIONS:

- Assess deep vein valvular competence
- Confirm a diagnosis of DVT
- Determine the cause of extremity swelling or pain
- Determine the source of emboli when pulmonary embolism is suspected or diagnosed
- Distinguish clot formation from venous obstruction
- Evaluate congenital venous malformations
- Locate a vein for arterial bypass graft surgery

RESULT

Normal Findings: No obstruction to flow or filling defects after injection of radiopaque dye; steady opacification of superficial and deep vasculature with no filling defects

Abnormal Findings: Abnormal results may indicate DVT, deep vein valvular incompetence, or venous obstruction

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.
- Patients with bleeding disorders.

Factors that may impair clear imaging:

- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment

- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Movement of the leg being tested, excessive tourniquet constriction, insufficient injection of contrast medium, and delay between injection and the x-ray
- Severe edema of the legs, making venous access impossible
- Weight bearing on the leg being tested, which prevents the contrast medium from filling the veins

Other considerations:

- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue can produce erroneous hot spots.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the venous system of the lower extremities.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, and dyes), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular system, as well as results of previously performed laboratory tests (especially coagulation tests, blood urea nitrogen, and creatinine, if contrast medium is to be used), surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Cardiovascular System table.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Inform the patient that the procedure is performed in a special department, usually in a radiology or vascular suite, by a health care practitioner and support staff, and takes approximately 30 to 60 minutes.
- Explain that an intravenous (IV) line may be inserted to allow infusion of IV fluids, contrast medium, dye, or

sedatives. Usually normal saline is infused.

- Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.
- *Sensitivity to social and cultural issues*, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure
- The patient should fast and restrict fluids for 8 hours prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.
- Patients receiving metformin (glucophage) for non–insulin dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hours after the test. Failure to do so may result in lactic acidosis.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects in the area to be examined.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*
- This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.

Intratest:

- Ensure that the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations; assure that food and medications have been restricted for at least 8 hours prior to the procedure. Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs and assess neurologic status. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.
- Using a pen, mark the site of the patient's peripheral pulses before angiography; this allows for quicker and more consistent assessment of the pulses after the procedure.
- Place the patient in the supine position on an exam table. Cleanse the selected area, and cover with a sterile drape.
- A local anesthetic is injected at the site, and a small incision is made or a needle inserted under fluoroscopy.
- The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined. Delayed images

may be taken to examine the vessels after a time and to monitor the venous phase of the procedure.

- Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- The results are recorded on x-ray film or electronically, in a computerized system, for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the health care practitioner. Renal function should be assessed before metformin is resumed.
- Monitor vital signs and neurologic status every 15 minutes for 1 hour, then every 2 hours for 4 hours, and then as ordered by the health care practitioner. Take temperature every 4 hours for 24 hours. Compare with baseline values. Notify the health care practitioner if temperature is elevated. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation. Note any pleuritic pain, persistent right shoulder pain, or abdominal pain.
- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema. Instruct the patient in the care and assessment of the site.
- Instruct the patient to maintain bed rest for 4 to 6 hours after the procedure or as ordered.
- *Nutritional considerations:* A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corre-

sponding literature provided by a pharmacist.

- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the abdomen, computed tomography angiography, lung perfusion scan, magnetic resonance angiography, magnetic resonance imaging of the abdomen, renogram, and peripheral Doppler ultrasound.

VERTEBROPLASTY

SYNONYMS/ACRONYM: None.

AREA OF APPLICATION: Spine.

CONTRAST: Intravenous iodine based.

DESCRIPTION & RATIONALE: Vertebroplasty is a minimally invasive, nonsurgical therapy used to repair a broken vertebra and to provide relief of pain related to vertebral compression in the spine that has been weakened by osteoporosis or tumoral lesions. Osteoporosis affects over 10 million women in the United States and accounts for over 700,000 vertebral fractures per year. This procedure is usually successful at alleviating the pain caused by a compression fracture less than 6 months in duration with pain directly referable to the location of the fracture. Secondary benefits may include vertebra stabilization and reduction of the risk of further compression. This procedure is usually performed on an outpatient basis. The procedure is accomplished by injecting orthopedic cement mixture through a needle into a fracture site. Vertebroplasty may be the perferred procedure when patients are too elderly or frail to tolerate open spinal surgery, or with bones too weak for surgical repair. Patients with a malignant tumor may possibly benefit from vertebroplasty. Other possible applications include younger patients whose osteoporosis is caused by long-term steroid use or a metabolic disorder. This procedure is recommended after basic treatments such as bed rest and orthopedic braces have failed, or pain medication has been ineffective or caused the patient medical problems, including stomach ulcers. ■

INDICATIONS:

- Assist in the detection of nonmalignant tumors before surgical resection.
- Repair of compression spinal fractures

of varying ages. Fractures older than 6 months will respond but at a slower rate. Fractures less than 4 weeks old should be give a chance to heal without intervention unless they are associated with disabling pain or hospitalization.

- Repair of spinal problems due to tumors.

Result

Normal Findings:

- Improvement in the ability to ambulate without pain
- Relief of back pain

Abnormal Findings:

- Failure to reduce the patient's pain
- Failure to improve the patient's mobility

Interfering Factors

This procedure is contraindicated for:

- ⚠ Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Pain that is primarily radicular in nature
- Patients with bleeding disorders
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
- Pain that is improving or that has been present and unchanged for years
- Imaging procedures that suggest no fracture is present or that the fracture is remote from the patient's pain

Factors that may impair clear imaging:

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings, dental amalgams), which may inhibit organ visualization and can produce unclear images
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined

Other considerations:

- Complications of the procedure include hemorrhage, infection at the insertion site, and cardiac arrhythmias.
- The procedure may be terminated if chest pain, or severe cardiac arrhythmias occur.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic

overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure improves the spinal column function.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, and dyes), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's musculoskeletal system, as well as results of previously performed laboratory tests (especially coagulation tests, blood urea nitrogen, and creatinine, if contrast medium is to be used), surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Musculoskeletal System table.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Inform the patient that the procedure is performed in the radiology department by a health care practitioner and support staff, and takes approximately 30 to 90 minutes.
- Explain that an intravenous (IV) line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- The patient should fast and restrict fluids for 8 hours prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.
- Instruct the patient to remove jewelry (including watches), hairpins, credit cards, and other metallic objects from the area to be examined.
- *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*
- This procedure may be terminated if chest pain or severe cardiac arrhythmias occur.

Intratest:

- Ensure that the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations; assure that these have been restricted for at least 8 hours prior to

the procedure. Ensure that the patient has removed all external metallic objects (jewelry, dentures, etc.) prior to the procedure.

- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs and assess neurologic status. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.
- Using a pen, mark the site of the patient's peripheral pulses before angiography; this allows for quicker and more consistent assessment of the pulses after the procedure.
- Place the patient in the prone position on an exam table. Cleanse the selected area, and cover with a sterile drape.
- A local anesthetic is injected at the site, and a small incision is made or a needle inserted under fluoroscopy.
- Ask the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- Orthopedic cement is injected through the needle into the fracture.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- The results are recorded manually, on x-ray film, or electronically, in a computerized system, for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the health care practitioner.
- Monitor vital signs and neurologic status every 15 minutes for 1 hour, then every 2 hours for 4 hours, and then as ordered by the health care practitioner. Take temperature every 4 hours for 24 hours. Compare with baseline values. Notify the health care practitioner if temperature is elevated. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation. Note any

pleuritic pain, persistent right shoulder pain, or abdominal pain.

- Instruct the patient to apply cold compresses to the puncture site, as needed, to reduce discomfort or edema. Instruct the patient in the care and assessment of the site.
- Instruct the patient to maintain bed rest for 4 to 6 hours after the procedure or as ordered.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to physical activity. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include bone mineral densitometry, bone scan, computed tomography of the spine, and magnetic resonance imaging of the spine.

VISUAL FIELDS TEST

SYNONYMS/ACRONYMS: Perimetry, VF.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION & RATIONALE: The visual field is the area within which objects can be seen by the eye as it fixes on a central point. The central field is an area extending 25° surrounding the fixation point. The peripheral field is the remainder of the area within which objects can be viewed. This test evaluates the central visual field through systematic movement of the test object across a tangent screen. It tests the function of the retina, optic nerve, and optic pathways. Visual field testing may be kinetic or static. Kinetic testing (confrontation, Goldmann or tangent screen) involves the movement of a visual stimulus to different areas and marking the point at which it is first seen by the patient. Static testing is performed using automated and computerized equipment. A specific point is chosen in stationary or static examinations, and the stimulus is increased until its threshold is determined. Tangent screen testing is the most common visual field test and is described in greater detail in this monograph. ■

INDICATIONS:

- Detect field vision loss and evaluate its progression or regression

RESULT

Normal Findings:

- Normal central vision field will form a circle extending 25° superiorly, nasally, inferiorly, and temporally; 12° to 15° temporal to the central fixation point is a physiologic blind spot, approximately 1.5° below the horizontal meridian. It is approximately 7.5° high and 5.5° wide. The patient should be able to see the test object throughout the entire central vision field except within the physiologic blind spot.

Abnormal Findings:

- Amblyopia
- Blepharochalasis
- Blurred vision
- Brain tumors
- Cerebrovascular accidents
- Chorodial nevus
- Diabetes with ophthalmic manifestations
- Glaucoma
- Headache
- Macular degeneration
- Macular drusen
- Nystagmus
- Optic neuritis or neuropathy
- Ptosis of eyelid
- Retinal detachment, hole, or tear
- Retinal exudates or hemorrhage
- Retinal occlusion of the artery or vein
- Retinitis pigmentosa
- Subjective visual disturbance
- Use of high-risk medications
- Visual field defect
- Vitreous traction syndrome

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair the results of the examination:

- An uncooperative patient or a patient with severe vision loss who has dificulty seeing even a large vision screen may have test results that are invalid.
- Assess and make note of the patient's cooperation and reliability as good,

fair, or poor, because it is difficult to evaluate factors such as general health, fatigue, or reaction time that affect test performance.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure detects visual field function.
- Obtain a history of the patient's complaints, including a list of known allergens.
- Obtain a history of the patient's known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- Obtain a history of results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the table of tests associated with the Ocular System.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Measurement of visual acuity with and without corrective lenses prior to testing is highly recommended. Instruct the patient to wear corrective lenses, if appropriate and if worn to correct for distance vision. Instruct the patient regarding the importance of keeping the eyes open for the test.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that no discomfort will be experienced during the test. Inform the patient that a technician, optometrist, or physician performs the test, in a quiet, darkened room, and that to evaluate both eyes, the test can take up 30 minutes.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- Seat the patient 1 to 2 meters away from the tangent screen with the eye being tested directly in line with the central fixation tangent, usually a white disk, on the screen. Ask the patient to place the chin in the chin rest and gently press the forehead against the support bar. Reposition the patient as appropriate to ensure the eye(s) to be tested are properly aligned in front of the visual field testing equipment.
- The results are recorded manually or on a paper strip from the automated equipment for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and encourage the patient to recognize and be supportive of impaired activity related to vision loss, perceived loss of driving privileges, or the possibility of requiring corrective lenses (self-image). Discuss the implications of the test results on the patient's lifestyle.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider.

- Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Instruct the patient in the use and cleaning of other devices (e.g., a hearing aid). Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include fluoroscein angiography, fundus photography, gonioscopy, intraocular pressure, and slit-lamp biomicroscopy.

VITAMIN B_{12}

SYNONYM/ACRONYM: Cyanocobalamin.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Immunochemiluminescent assay)

Age	Conventional Units	SI Units (Conventional Units × 0.738)
Newborn	160–1300 pg/mL	118–959 pmol/L
Adult	200–900 pg/mL	148–664 pmol/L

DESCRIPTION & RATIONALE: Vitamin B_{12} has a ringed crystalline structure that surrounds an atom of cobalt. It is essential in DNA synthesis, hematopoiesis, and central nervous system integrity. It is derived solely from dietary intake. Animal products are the richest source of vitamin B_{12}. Its absorption depends on the presence of intrinsic factor. Circumstances that may result in a deficiency of this vitamin include the presence of stomach or intestinal disease as well as insufficient dietary intake of foods containing vitamin B_{12}. A significant increase in red blood cell (RBC) mean corpuscular volume may be an important indicator of vitamin B_{12} deficiency. ■

INDICATIONS:

- Assist in the diagnosis of central nervous system disorders
- Assist in the diagnosis of megaloblastic anemia
- Evaluate alcoholism
- Evaluate malabsorption syndromes

RESULT

Increased in:

- Chronic granulocytic leukemia
- Chronic obstructive pulmonary disease
- Chronic renal failure
- Diabetes
- Leukocytosis
- Liver cell damage (hepatitis, cirrhosis)
- Obesity
- Polycythemia vera
- Protein malnutrition
- Severe congestive heart failure
- Some carcinomas

Decreased in:

- Abnormalities of cobalamin transport or metabolism
- Bacterial overgrowth
- Crohn's disease
- Dietary deficiency (e.g., in vegetarians)
- *Diphyllobothrium* (fish tapeworm) infestation
- Gastric or small intestine surgery
- Hypochlorhydria
- Inflammatory bowel disease
- Intestinal malabsorption
- Intrinsic factor deficiency
- Late pregnancy
- Pernicious anemia

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase vitamin B_{12} levels include chloral hydrate.
- Drugs that may decrease vitamin B_{12} levels include alcohol, aminosalicylic acid, anticonvulsants, ascorbic acid, cholestyramine, cimetidine, colchicine, metformin, neomycin, oral contraceptives, ranitidine, and triamterene.
- Hemolysis or exposure of the specimen to light invalidates results.
- Specimen collection soon after blood transfusion can falsely increase vitamin B_{12} levels.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to diagnose and monitor vitamin B_{12} and folic acid deficiency.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal and hematopoietic systems as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Gastrointestinal and Hematopoietic System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient is regularly using these products so that their

effects can be taken into consideration when reviewing results.

- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- Instruct the patient to fast for at least 12 hours before specimen collection.
- There are no fluid or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 12 hours prior to the procedure.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube. Protect the specimen from light.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- Instruct the patient to resume usual diet, as directed by the health care practitioner.
- *Nutritional considerations:* Instruct the patient with a deficiency of vitamin B_{12}, as appropriate, in the use of vitamin supplements. Inform the patient, as appropriate, that the best dietary sources of vitamin B_{12} are meats, fish, poultry, eggs, and milk.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include complete blood count, folate, homocysteine, intrinsic factor antibodies, peripheral blood smear for RBC morphology and presence of hypersegmented neutrophils, and RBC indices for mean corpuscular volume.

VITAMIN D

SYNONYMS/ACRONYM: Cholecalciferol, vitamin D 1,25-dihydroxy.

SPECIMEN: Serum (1 mL) collected in a red-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Radiobinding assay for vitamin D 25-dihydroxy, radioreceptor assay for vitamin D 1,25-dihydroxy)

Form	Conventional Units	SI Units (Conventional Units × 2.496)
Vitamin D 25-dihydroxy	9–52 ng/mL	22.5–129.8 nmol/L
Vitamin D 1,25-dihydroxy	15–60 pg/mL	37.4–149.8 pmol/L

DESCRIPTION & RATIONALE: There are two metabolically active forms of vitamin D. Ergocalciferol (vitamin D_2) is formed when ergosterol in plants is exposed to sunlight. Ergocalciferol is absorbed by the stomach and intestine when orally ingested. Cholecalciferol (vitamin D_3) if formed when the skin is exposed to sunlight or ultraviolet light. Vitamins D_2 and D_3 enter the bloodstream after absorption. Vitamin D_3 is converted to vitamin D 25-hydroxy by the liver and is the major circulating form of the vitamin. Vitamin D_2 is converted to vitamin D 1,25-dihydroxy by the kidneys and is the more biologically active form. Vitamin D acts with parathyroid hormone and calcitonin to regulate calcium metabolism and osteoblast function. ■

INDICATIONS:

- Differential diagnosis of disorders of calcium and phosphorus metabolism
- Evaluate deficiency or suspected toxicity
- Investigate bone diseases
- Investigate malabsorption

RESULT

Increased in:

- Vitamin D intoxication

Decreased in:

- Bowel resection
- Celiac disease
- Inflammatory bowel disease
- Malabsorption
- Osteitis fibrosa cystica
- Osteomalacia
- Pancreatic insufficiency
- Rickets
- Thyrotoxicosis

CRITICAL VALUES:

Vitamin toxicity can be as significant as problems brought about by vitamin deficiencies. The potential for toxicity is especially important to consider with respect to fat-soluble vitamins, which are not eliminated from the body as quickly as water-soluble vitamins and can accumulate in the body. Most cases of toxicity are brought about by oversupplementing and can be avoided by consulting a qualified nutritionist for recommended daily dietary and supplemental allowances. Signs and symptoms of vitamin D toxicity include nausea, loss of appetite, vomiting, polyuria, muscle weakness, and constipation.

INTERFERING FACTORS:

- Drugs that may increase vitamin D levels include etidronate disodium and pravastatin.
- Drugs and substances that may decrease vitamin D levels include aluminum hydroxide, anticonvulsants, cholestyramine, colestipol, glucocorticoids, isoniazid, mineral oil, and rifampin.
- Recent radioactive scans or radiation within 1 week before the test can interfere with test results when radioimmunoassay is the test method.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate vitamin D toxicity or deficiency.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal and musculoskeletal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Gastrointestinal and Musculoskeletal System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Educate the patient with vitamin D deficiency, as appropriate, that the main dietary sources of vitamin D are fortified dairy foods and cod liver oil. Explain to the patient that vitamin D is also synthesized by the body, in the skin, and is activated by sunlight.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include blood and urine calcium, kidney stone analysis, osteocalcin, and phosphorus.

VITAMIN E

SYNONYM/ACRONYM: α-Tocopherol.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: High-performance liquid chromatography)

Age	Conventional Units	SI Units (Conventional Units × 23.22)
1–12 y	0.3–0.9 mg/dL	7–21 μmol/L
13–19 y	0.6–1.0 mg/dL	14–23 μmol/L
Adult	0.5–1.8 mg/dL	12–42 μmol/L

DESCRIPTION & RATIONALE: Vitamin E is a powerful fat-soluble antioxidant that prevents the oxidation of unsaturated fatty acids, which can combine with polysaccharides to form deposits in tissue. For this reason,

vitamin E is believed to reduce the risk of coronary artery disease. Vitamin E reserves in lung tissue provide a barrier against air pollution and protect red blood cell membrane integrity from oxidation. Oxidation of fatty acids in red blood cell membranes can result in irreversible membrane damage and hemolysis. Studies are in progress to confirm the suspicion that oxidation also contributes to the formation of cataracts and macular degeneration of the retina. Because vitamin E is found in a wide variety of foods, a deficiency secondary to inadequate dietary intake is rare. ■

INDICATIONS:

- Evaluate neuromuscular disorders in premature infants and adults
- Evaluate patients with malabsorption disorders
- Evaluate suspected hemolytic anemia in premature infants and adults
- Monitor patients on long-term parenteral nutrition

RESULT

Increased in:

- Obstructive liver disease
- Vitamin E intoxication

Decreased in:

- Abetalipoproteinemia
- Hemolytic anemia
- Malabsorption disorders, such as biliary atresia, cirrhosis, cystic fibrosis, chronic pancreatitis, pancreatic carcinoma, and chronic cholestasis

CRITICAL VALUES:

Vitamin toxicity can be as significant as problems brought about by vitamin deficiencies. The potential for toxicity is especially important to consider with respect to fat-soluble vitamins, which are not eliminated from the body as quickly as water-soluble vitamins and can accumulate in the body. Most cases of toxicity are brought about by oversupplementing and can be avoided by consulting a qualified nutritionist for recommended daily dietary and supplemental allowances. *Note:* Excessive supplementation of vitamin E (greater than 60 times the Recommended Dietary Allowance over a period of 1 year or longer) can result in excessive bleeding, delayed healing of wounds, and depression.

INTERFERING FACTORS:

- Drugs that may increase vitamin E levels include anticonvulsants (in women).
- Drugs that may decrease vitamin E levels include anticonvulsants (in men).
- Exposure of the specimen to light decreases vitamin E levels, resulting in a falsely low result.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate vitamin E toxicity or deficiency.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's cardiovascular, gastrointestinal, hematopoietic, and hepatobiliary systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Cardiovascular, Gastrointestinal, Hematopoietic, and Hepatobiliary System tables.

- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or tiger-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Educate the patient with a vitamin E deficiency, if appropriate, that the main dietary sources of vitamin E are vegetable oils, whole grains, wheat germ, milk, eggs, meats, fish, and green leafy vegetables. Vitamin E is fairly stable at most cooking temperatures (except frying) and when exposed to acidic foods.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

VITAMIN K

SYNONYMS/ACRONYM: Phylloquinone, phytonadione.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: High-performance liquid chromatography)

Conventional Units	SI Units (Conventional Units × 2.22)
0.13–1.19 ng/mL	0.29–2.64 nmol/L

DESCRIPTION & RATIONALE: Vitamin K is one of the fat-soluble vitamins. It is essential for the formation of prothrombin; factors VII, IX, and X; and proteins C and S. Vitamin K also works with vitamin D in synthesizing bone protein, and regulating calcium levels (see monograph titled "Vitamin D.") Vitamin K levels are not often requested, but vitamin K is often prescribed as a medication. Approximately one-half of the body's vitamin K is produced by intestinal bacteria; the other half is obtained from dietary sources. There are three forms of vitamin K: vitamin K_1, or phylloquinone, which is found in foods; vitamin K_2, or menaquinone, which is synthesized by intestinal bacteria; and vitamin K_3, or menadione, which is the synthetic, water-soluble, pharmaceutical form of the vitamin. Vitamin K_3 is two to three times more potent than the naturally occurring forms. ■

INDICATIONS: Evaluation of bleeding of unknown cause (e.g., frequent nosebleeds, bruising)

RESULT

Increased in:

- Excessive administration of vitamin K

Decreased in:

- Antibiotic therapy (by decreasing intestinal flora)
- Chronic fat malabsorption
- Cystic fibrosis
- Diarrhea (in infants)
- Gastrointestinal disease
- Hemorrhagic disease of the newborn
- Hypoprothrombinemia
- Liver disease
- Obstructive jaundice
- Pancreatic disease

CRITICAL VALUES: Vitamin toxicity can be as significant as problems brought about by vitamin deficiencies. The potential for toxicity is especially important to consider with respect to fat-soluble vitamins, which are not eliminated from the body as quickly as water-soluble vitamins and can accumulate in the body. The naturally occurring forms, vitamin K_1 and K_2, do not cause toxicity. Signs and symptoms of vitamin K_3 toxicity include bleeding and jaundice. Possible interventions include withholding the source.

INTERFERING FACTORS: Drugs and substances that may decrease vitamin K levels include antibiotics, cholestyramine, coumarin, mineral oil, and warfarin.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assist in the evaluation of symptoms relating to chronic antibiotic therapy and investigation of bleeding of unknown etiology.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic and hepatobiliary systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic and Hepatobiliary System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Inform the patient with a vitamin K deficiency, as appropriate, that the main dietary sources of vitamin K are cabbage, cauliflower, spinach and other green leafy vegetables, pork, liver, soybeans, and vegetable oils.

- Instruct the patient to report bleeding from any areas of the skin or mucous membranes.
- Inform the patient of the importance of taking precautions against bleeding or bruising, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of aspirin products, and avoidance of intramuscular injections.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include antithrombin III and prothrombin time.

VITAMINS A, B_1, B_6, AND C

SYNONYMS/ACRONYMS: Vitamin A: retinol, carotene; vitamin B_1: thiamine; vitamin B_6: niacin, pyroxidine, P-5'-P, pyridoxyl-5-phosphate; vitamin C: ascorbic acid.

SPECIMEN: Serum (1 mL) collected in a red-top tube each for vitamins A and C; plasma (1 mL) collected in a lavender-top (EDTA) tube each for vitamins B_1 and B_6.

REFERENCE VALUE: (Method: Chromatography for vitamins A, B_1, and B_6; capillary electrophoresis for vitamin C)

Vitamin	Age	Conventional Units	SI Units
			(Conversion Factor × 0.0349)
Vitamin A	1–6 y	20–43 μg/dL	0.70–1.50 μmol/L
	7–12 y	26–49 μg/dL	0.91–1.71 μmol/L
	13–19 y	26–72 μg/dL	0.91–2.51 μmol/L
	Adult	30–80 μg/dL	1.05–2.80 μmol/L

(*Continued on the following page*)

Vitamin	Age	Conventional Units	SI Units
			(Conversion Factor × 29.6)
Vitamin B_1		0.21–0.43 μg/dL	6.2–12.8 μmol/L
			(Conversion Factor × 4.046)
Vitamin B_6		5–30 ng/mL	20–121 nmol/L
			(Conversion Factor × 56.78)
Vitamin C		0.2–1.9 mg/dL	11.4–107.9 μmol/L

DESCRIPTION & RATIONALE: Vitamin assays are used in the measurement of nutritional status. Low levels indicate inadequate oral intake, poor nutritional status, or malabsorption problems. High levels indicate excessive intake, vitamin intoxication, or absorption problems. Vitamin A is a fat-soluble nutrient that promotes normal vision and prevents night blindness; contributes to growth of bone, teeth, and soft tissues; supports thyroxine formation; maintains epithelial cell membranes, skin, and mucous membranes; and acts as an anti-infec-tion agent. Vitamins B_1, B_6, and C are water soluble. Vitamin B_1 acts as an enzyme and plays an important role in the Krebs cycle. Vitamin B_6 is important in heme synthesis and functions as a coenzyme in amino acid metabolism and glycogenolysis. It includes pyridoxine, pyridoxal, and pyridoxamine. Vitamin C promotes collagen synthesis, maintains capillary strength, facilitates release of iron from ferritin to form hemoglobin, and functions in the stress response. ■

INDICATIONS

Vitamin A:

- Assist in the diagnosis of night blindness
- Evaluate skin disorders
- Investigate suspected vitamin A deficiency

Vitamin B_1:

- Investigate suspected beriberi
- Monitor the effects of chronic alcoholism

Vitamin B_6:

- Investigate suspected malabsorption or malnutrition
- Investigate suspected vitamin B_6 deficiency

Vitamin C:

- Investigate suspected metabolic or malabsorptive disorders
- Investigate suspected scurvy

RESULT

Increases in:

- Vitamin A:
  Chronic kidney disease
  Idiopathic hypercalcemia in infants
  Vitamin A toxicity

Decreases in:

- Vitamin A:
  Abetalipoproteinemia
  Carcinoid syndrome
  Chronic infections
  Cystic fibrosis

Disseminated tuberculosis
Hypothyroidism
Infantile blindness
Liver, gastrointestinal, or pancreatic disease
Night blindness
Protein malnutrition
Sterility and teratogenesis
Zinc deficiency

- Vitamin B_1:
  Alcoholism
  Carcinoid syndrome
  Hartnup disease
  Pellagra
- Vitamin B_6:
  Alcoholism
  Asthma
  Carpal tunnel syndrome
  Gestational diabetes
  Lactation
  Malabsorption
  Malnutrition
  Neonatal seizures
  Normal pregnancies
  Occupational exposure to hydrazine compounds
  Pellagra
  Pre-eclamptic edema
  Renal dialysis
  Uremia
- Vitamin C:
  Alcoholism
  Anemia
  Cancer
  Hemodialysis
  Hyperthyroidism
  Malabsorption
  Pregnancy
  Rheumatoid disease
  Scurvy

CRITICAL VALUES:

Vitamin toxicity can be as significant as problems brought about by vitamin deficiencies. The potential for toxicity is especially important to consider with respect to fat-soluble vitamins, which are not eliminated from the body as quickly as water-soluble vitamins and can accumulate in the body. Most cases of toxicity are brought about by oversupplementing and can be avoided by consulting a qualified nutritionist for recommended daily dietary and supplemental allowances. Signs and symptoms of vitamin A toxicity may include headache, blurred vision, bone pain, joint pain, dry skin, and loss of appetite.

INTERFERING FACTORS:

- Drugs and substances that may increase vitamin A levels include alcohol (moderate intake), oral contraceptives, and probucol.
- Drugs and substances that may decrease vitamin A levels include alcohol (chronic intake, alcoholism), allopurinol, cholestyramine, colestipol, mineral oil, and neomycin.
- Drugs that may decrease vitamin B_1 levels include glibenclamide, isoniazid, and valproic acid.
- Drugs that may decrease vitamin B_6 levels include amiodarone, anticonvulsants, cycloserine, disulfiram, ethanol, hydralazine, isoniazid, levodopa, oral contraceptives, penicillamine, pyrazinoic acid, and theophylline.
- Drugs and substances that may decrease vitamin C levels include acetylsalicylic acid, aminopyrine, barbiturates, estrogens, heavy metals, oral contraceptives, nitrosamines, and paraldehyde.
- Chronic tobacco smoking decreases vitamin C levels.
- Various diseases may affect vitamin levels (see Results section).
- Diets high in freshwater fish and tea, which are thiamine antagonists, may cause decreased vitamin B_1 levels.

- Long-term hyperalimentation may result in decreased vitamin levels.
- Exposure of the specimen to light decreases vitamin levels, resulting in a falsely low results.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to assess hypervitaminosis or deficiency.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal, genitourinary, hepatobiliary, immune, and musculoskeletal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Gastrointestinal, Genitourinary, Hepatobiliary, Immune, and Musculoskeletal System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- Instruct the patient to fast for at least 12 hours before specimen collection for vitamin A.
- There are no fluid or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 12 hours prior to the vitamin A test.
- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red- or lavender-top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Educate the patient with a specific vitamin deficiency, as appropriate, regarding dietary sources of these vitamins. Advise the patient to ask a nutritionist to develop a diet plan recommended for his or her specific needs.

Vitamin A:

- The main source of vitamin A comes from carotene, a yellow pigment noticeable in most fruits and vegetables, especially carrots, sweet

potatoes, squash, apricots, and cantaloupe. It is also present in spinach, collards, broccoli, and cabbage. This vitamin is fairly stable at most cooking temperatures, but it is destroyed easily by light and oxidation.

Vitamin B_1:

- Vitamin B_1 is the most stable with respect to the effects of environmental factors. It is found in meats, coffee, peanuts, and legumes. The body is also capable of making some vitamin B_1 by converting the amino acid tryptophan to niacin.

Vitamin B_6:

- Good sources of vitamin B_6 include meats (especially beef and pork), whole grains, wheat germ, legumes, potatoes, oatmeal, and bananas. As with other water-soluble vitamins, it is best preserved by rapid cooking, although it is relatively stable at most cooking temperatures (except frying) and when exposed to acidic foods. This vitamin is destroyed rapidly by light and alkalis.

Vitamin C:

- Citrus fruits are excellent dietary sources of vitamin C. Other good sources are green and red peppers, tomatoes, white potatoes, cabbage, broccoli, chard, kale, turnip greens, asparagus, berries, melons, pineapple, and guava. Vitamin C is destroyed by exposure to air, light, heat, or alkalis. Boiling water before cooking eliminates dissolved oxygen that destroys vitamin C in the process of boiling. Vegetables should be crisp and cooked as quickly as possible.

General:

- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

WHITE BLOOD CELL COUNT AND CELL DIFFERENTIAL

SYNONYMS/ACRONYM: WBC with diff, leukocyte count, white cell count.

SPECIMEN: Whole blood from one full lavender-top (EDTA) tube.

REFERENCE VALUE: (Method: Automated, computerized, multichannel analyzers that sort and size cells on the basis of changes in either electrical impedance or light pulses as the cells pass in front of a laser. Many of these analyzers are capable of determining a five-part WBC differential.) The WBC count and differential enumerates and identifies granulocytes, lymphocytes, monocytes, eosinophils, and basophils.

Age	Conventional Units WBC × $10^3/mm^3$	Neutrophils		
		Total (Absolute) and %	*Bands (Absolute) and %*	*Segments (Absolute) and %*
Birth	9.0–30.0	(6.0–26.0) 61%	(1.65) 9.1%	(9.4) 52%
1 d	9.4–34.0	(5.0–21.0) 61%	(1.75) 9.2%	(9.8) 52%
2 wk	5.0–20.0	(1.0–9.5) 40%	(0.63) 5.5%	(3.9) 34%
1 mo	5.0–19.5	(1.0–9.0) 35%	(0.49) 4.5%	(3.3) 30%
6 mo	6.0–17.5	(1.0–8.5) 32%	(0.45) 3.8%	(3.3) 28%
1 y	6.0–17.5	(1.5–8.5) 31%	(0.35) 3.1%	(3.2) 28%
10 y	4.5–13.5	(1.8–8.0) 54%	(0–1.0) 3.0%	(1.8–7.0) 51%
Adult	4.5–11.0	(1.8–7.7) 59%	(0–0.7) 3.0%	(1.8–7.0) 56%

*SI Units (Conventional Units × 1 × 10^9/L or WBC × 1000/mm^3)

DESCRIPTION & RATIONALE: White blood cells (WBCs) constitute the body's primary defense system against foreign organisms, tissues, and other substances. The life span of a normal WBC is 13 to 20 days. Old WBCs are destroyed by the lymphatic system and excreted in the feces. The main WBC types are neutrophils, eosinophils, basophils, monocytes, and lymphocytes. They are produced in the bone marrow, although lymphocytes can be produced in other sites as well. The WBC count can be performed alone with the differential cell count or as part of the complete blood count (CBC). An increased WBC count is termed *leukocytosis,* and a decreased WBC count is termed *leukopenia.* A total WBC count indicates the degree of response to a pathologic process, but a more complete evaluation for specific diagnoses for any one disorder is provided by the differential count. The WBCs in the count and differential are reported as an *absolute value* and as a percentage. The relative percentages of cell types are arrived at by basing the enumeration of each cell type on a 100-cell count. The absolute value is obtained by multiplying the relative percentage value of each cell type by the total WBC count.

Acute leukocytosis is initially

Lymphocytes (Absolute) and %	Monocytes (Absolute) and %	Eosinophils (Absolute) and %	Basophils (Absolute) and %
(2.0–11) 31%	(0.4–3.1) 5.8%	(0.02–0.85) 2.2%	(0–0.64) 0.6%
(2.0–11.5) 31%	(0.2–3.1) 5.8%	(0.02–0.95) 2.0%	(0–0.30) 0.5%
(2.0–17.0) 48%	(0.2–2.4) 8.8%	(0.07–1.0) 3.1%	(0–0.23) 0.4%
(2.5–16.5) 56%	(0.15–2.0) 6.5%	(0.07–0.90) 2.8%	(0–0.20) 0.5%
(4.0–13.5) 61%	(0.1–1.3) 4.8%	(0.07–0.75) 2.5%	(0–0.20) 0.4%
(4.0–10.5) 61%	(0.05–1.1) 4.8%	(0.05–0.70) 2.6%	(0–0.20) 0.4%
(1.5–6.5) 38%	(0–0.8) 4.3%	(0–0.60) 2.4%	(0–0.20) 0.5%
(1.0–4.8) 34%	(0–0.8) 4.0%	(0–0.45) 2.7%	(0–0.20) 0.5%

accompanied by changes in the WBC count population, followed by changes within the individual WBCs. Leukocytosis usually occurs by way of increase in a single WBC family rather than a proportional increase in all cell types. Toxic granulation and vacuolation are commonly seen in leukocytosis accompanied by a *shift to the left,* or increase in the percentage of immature band neutrophils to mature segmented neutrophils. Bandemia is defined by the presence of greater than 6% band neutrophils in the total neutrophil cell population. These changes in the white cell population are most commonly associated with an infectious process, usually bacterial, but they can occur in healthy individuals who are under stress, such as women in childbirth and very young infants. The WBC count and differential of an actively crying infant may show an overall increase in WBCs with a shift to the left. Any stressful situation causing production of epinephrine results in a rapid increase in WBC count. Before initiating any kind of intervention, it is important to determine whether an increased WBC count is the result of a normal condition involving physiologic stress versus a pathologic processes. The use of multiple specimen types may confuse the interpretation of results in infants. Multiple samples from the same collection site (i.e., capillary versus venous) may be necessary to obtain an accurate assessment of the WBC picture in these young patients.

Neutrophils are normally found as the predominant WBC type in the circulating blood. Also called *polymorphonuclear cells,* they are the body's first line of defense through the process of phagocytosis. They also contain enzymes and pyogens, which combat foreign invaders.

Lymphocytes are agranular, mononuclear blood cells that are smaller than granulocytes. They are found in the next highest percentage in normal circulation. Lymphocytes are classified as B cells and T cells. Both types are formed in the bone marrow, but B cells mature in the bone marrow and T cells mature in the thymus. Lymphocytes play a major role in the body's natural defense system. B cells differentiate into immunoglobulin-synthesizing plasma cells. T cells function as cellular mediators of immunity and comprise helper/inducer (CD4) lymphocytes, delayed hypersensitivity lymphocytes, cytotoxic (CD8 or CD4) lymphocytes, and suppressor (CD8) lymphocytes.

Monocytes are mononuclear cells similar to lymphocytes, but they are related more closely to granulocytes in terms of their function. They are formed in the bone marrow from the same cells as those that produce neutrophils. The major function of monocytes is phagocytosis. Monocytes stay in the peripheral blood for about 70 hours, after which they migrate into the tissues and become macrophages.

The function of eosinophils is phagocytosis of antigen-antibody complexes. They become active in the later stages of inflammation. Eosinophils respond to allergic and parasitic diseases: They have granules that contain histamine used to kill foreign cells in the body and proteolytic enzymes that damage parasitic worms (see monograph titled "Eosinophil Count").

Basophils are found in small numbers in the circulating blood. They have a phagocytic function and, similar to eosinophils, contain numerous

specific granules. Basophilic granules contain heparin, histamines, and serotonin. Basophils may also be found in tissue and as such are classified as mast cells. Basophilia is noted in conditions such as leukemia, Hodgkin's disease, polycythemia vera, ulcerative colitis, nephrosis, and chronic hypersensitivity states. ■

INDICATIONS:

- Assist in confirming suspected bone marrow depression
- Assist in determining the cause of an elevated WBC count (e.g., infection, inflammatory process)
- Detect hematologic disorder, neoplasm, or immunologic abnormality
- Determine the presence of a hereditary hematologic abnormality
- Monitor the effects of physical or emotional stress
- Monitor the progression of nonhematologic disorders, such as chronic obstructive pulmonary disease, malabsorption syndromes, cancer, and renal disease
- Monitor the response to drugs or chemotherapy, and evaluate undesired reactions to drugs that may cause blood dyscrasias
- Provide screening as part of a CBC in a general physical examination, especially on admission to a health care facility or before surgery

RESULT

Increased in (leukocytosis):

- Normal physiologic and environmental conditions:
  Early infancy
  Emotional stress
  Exposure to cold
  Increased epinephrine secretion
  Menstruation
  Pregnancy and labor
  Strenuous exercise
  Ultraviolet light
- Pathologic conditions:
  Acute hemolysis, transfusion reactions
  All types of infections
  Anemias
  Appendicitis
  Collagen disorders
  Cushing's disease
  Inflammatory disorders
  Leukemias and other malignancies
  Parasitic infestations
  Polycythemia vera

Decreased in (leukopenia):

- Normal physiologic conditions:
  Diurnal rhythms
- Pathologic conditions:
  Alcoholism
  Anemias
  Bone marrow depression
  Malaria
  Malnutrition
  Radiation
  Rheumatoid arthritis
  Systemic lupus erythematosus (SLE) and other autoimmune disorders
  Toxic and antineoplastic drugs
  Viral infections

Neutrophils increased (neutrophilia):

- Acute hemolysis
- Acute hemorrhage
- Extremes in temperature
- Infectious diseases
- Inflammatory conditions (rheumatic fever, gout, rheumatoid arthritis, vasculitis, myositis)

- Malignancies
- Metabolic disorders (uremia, eclampsia, diabetic ketoacidosis, thyroid storm, Cushing's syndrome)
- Myelocytic leukemia
- Physiologic stress (e.g., allergies, asthma, exercise, childbirth, surgery)
- Tissue necrosis (burns, crushing injuries, abscesses, myocardial infarction)
- Tissue poisoning with toxins and venoms

Neutrophils decreased (neutropenia):

- Acromegaly
- Addison's disease
- Anaphylaxis
- Anorexia nervosa, starvation, malnutrition
- Bone marrow depression (viruses, toxic chemicals, overwhelming infection, radiation, Gaucher's disease)
- Disseminated SLE
- Thyrotoxicosis
- Viral infection (mononucleosis, hepatitis, influenza)
- Vitamin B_{12} or folate deficiency

Lymphocytes increased (lymphocytosis):

- Addison's disease
- Felty's syndrome
- Infections
- Lymphocytic leukemia
- Lymphomas
- Lymphosarcoma
- Myeloma
- Rickets
- Thyrotoxicosis
- Ulcerative colitis
- Waldenström's macroglobulinemia

Lymphocytes decreased (lymphopenia):

- Antineoplastic drugs
- Aplastic anemia
- Bone marrow failure
- Burns
- Gaucher's disease
- Hemolytic disease of the newborn
- High doses of adrenocorticosteroids
- Hodgkin's disease
- Hypersplenism
- Immunodeficiency diseases
- Malnutrition
- Pernicious anemia
- Pneumonia
- Radiation
- Rheumatic fever
- Septicemia
- Thrombocytopenic purpura
- Toxic chemical exposure
- Transfusion reaction

Monocytes increased (monocytosis):

- Carcinomas
- Cirrhosis
- Collagen diseases
- Gaucher's disease
- Hemolytic anemias
- Hodgkin's disease
- Infections
- Lymphomas
- Monocytic leukemia
- Polycythemia vera

- Radiation
- Sarcoidosis
- SLE
- Thrombocytopenic purpura
- Ulcerative colitis

CRITICAL VALUES:

Less than 2.5 WBC $\times$ 10^3/mm^3 or 2500 WBC/mm^3 (on admission)

Greater than 30.0 WBC $\times$ 10^3/mm^3 or 30,000 WBC/mm^3 (on admission)

Note and immediately report to the health care practitioner any critically increased or decreased values and related symptoms. The presence of abnormal cells, other morphologic characteristics, or cellular inclusions may signify a potentially life-threatening or serious health condition and should be investigated. Examples are hypersegmented neutrophils, agranular neutrophils, blasts or other immature cells, Auer rods, Döhle bodies, marked toxic granulation, or plasma cells.

INTERFERING FACTORS:

- Drugs that may decrease the overall WBC count include acetyldigitoxin, acetylsalicylic acid, aminoglutethimide, aminopyrine, aminosalicylic acid, ampicillin, amsacrine, antazoline, anticonvulsants, antineoplastic agents (therapeutic intent), antipyrine, barbiturates, busulfan, carbutamide, carmustine, chlorambucil, chloramphenicol, chlordane, chlorophenothane, chlortetracycline, chlorthalidone, cisplatin, colchicine, colistimethate, cycloheximide, cyclophosphamide, cytarabine, dacarbazine, dactinomycin, diaprim, diazepam, diethylpropion, digitalis, dipyridamole, dipyrone, fumagillin, glaucarubin, glucosulfone, hexachlorobenzene, hydroflumathiazide, hydroxychloroquine, iothiouracil, iproniazid, lincomycin, local anesthetics, mefenamic acid, mepazine, meprobamate, mercaptopurine, methotrexate, methylpromazine, mitomycin, paramethadione, parathion, penicillin, phenacemide, phenindione, phenothiazine, pipamazine, prednisone (by Coulter S method), primaquine, procainamide, procarbazine, prochlorperazine, promazine, promethazine, pyrazolones, quinacrine, quinines, radioactive compounds, razoxane, ristocetin, sulfa drugs, tamoxifen, tetracycline, thenalidine, thioridazine, tolazamide, tolazoline, tolbutamide, trimethadione, and urethan.
- A significant decrease in basophil count occurs rapidly after intravenous injection of propanidid and thiopental.
- A significant decrease in lymphocyte count occurs rapidly after administration of corticotropin, mechlorethamine, methylsergide, and x-ray therapy; and after megadoses of niacin, pyradoxine, and thiamine.
- Drugs that may increase the overall WBC count include amphetamine, amphotericin B, chloramphenicol, chloroform (normal response to anesthesia), colchicine (leukocytosis follows leukopenia), corticotropin, erythromycin, ether (normal response to anesthesia), fluroxene (normal response to anesthesia), isoflurane (normal response to anesthesia), niacinamide, phenylbutazone, prednisone, and quinine.
- Drug allergies may have a significant effect on eosinophil count and may affect the overall WBC count. Refer to the specific monograph for a detailed listing of interfering drugs.
- The WBC count may vary depending on the patient's position, decreasing when the patient is recumbent owing to hemodilution and increasing when the patient rises owing to hemoconcentration.
- Venous stasis can falsely elevate results; the tourniquet should not be left on the arm for longer than 60 seconds.
- Failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may

yield inadequate sample volume for automated analyzers and may be reason for specimen rejection.

- Hemolyzed or clotted specimens should be rejected for analysis.
- The presence of nucleated red blood cells or giant or clumped platelets affects the automated WBC, requiring a manual correction of the WBC count.
- Care should be taken in evaluating the CBC during the first few hours after transfusion.
- Patients with cold agglutinins or monoclonal gammopathies may have a falsely decreased WBC count as a result of cell clumping.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is primarily used to evaluate viral and bacterial infections and to diagnose and monitor leukemic disorders.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's hematopoietic, immune, and respiratory systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Hematopoietic, Immune, and Respiratory System tables.
- Note any recent procedures that can interfere with test results.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL lavender-top tube. The specimen should be mixed gently by inverting the tube 10 times. It is stable when stored for up to 6 hours at room temperature or 24 hours if stored refrigerated. In addition, if it is anticipated that the specimen will not be analyzed within 4 to 6 hours, two blood smears should be made immediately after the venipuncture and submitted with the blood sample.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Infection, fever, sepsis, and trauma can result in an impaired nutritional status. Malnutrition can occur for many reasons, including fatigue, lack of appetite, and gastrointestinal distress.
- *Nutritional considerations:* Adequate intake of vitamins A and C are also important for regenerating body stores depleted by the effort exerted in fighting infections. Educate the patient or caregiver regarding the importance of following the prescribed diet.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the National Cancer Institute *(http:// www.nci.nih.org)*.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include albumin, anti–cytoplasmic neutrophilic antibody, bone marrow biopsy, lymph node biopsy, eosinophil count, infectious mononucleosis, leukocyte alkaline phosphatase, other tests included in a CBC, peripheral blood smear, and zinc.

WHITE BLOOD CELL SCAN

SYNONYMS/ACRONYM: WBC imaging, inflammatory scan, labeled leukocyte scan, infection scintigraphy, labeled autologous leukocytes.

AREA OF APPLICATION: Whole body.

CONTRAST: Intravenous radionuclide combined with white blood cells.

DESCRIPTION & RATIONALE: Because white blood cells (WBCs) naturally accumulate in areas of inflammation, the WBC scan uses radiolabeled WBCs to help determine the site of an acute infection or confirm the presence or absence of infection or inflammation at a suspected site. A gamma camera detects the radiation emitted from the injected radionuclide, and a representative image of the radionuclide distribution is obtained and recorded on film or stored electronically. Because of its better image resolution and greater specificity for acute infections, the WBC scan has replaced scanning with gallium-67 citrate (Ga-67). Some chronic infections associated with pulmonary disease, however, may be better imaged with Ga-67. The WBC scan is especially helpful in detecting postoperative infection sites and in documenting lack of residual infection after a course of therapy. ■

INDICATIONS:

- Aid in the diagnosis of infectious or inflammatory diseases
- Differentiate infectious from noninfectious process
- Evaluate the effects of treatment
- Evaluate inflammatory bowel disease
- Evaluate patients with fever of unknown origin
- Evaluate postsurgical sites and wound infections
- Evaluate suspected infection of an orthopedic prosthesis
- Evaluate suspected osteomyelitis

RESULT

Normal Findings:

- No focal localization of the radionuclide, along with some slight localization of the radionuclide within the reticuloendothelial system (liver, spleen, and bone marrow)

Abnormal Findings:

- Abscess
- Arthritis
- Infection
- Inflammation
- Inflammatory bowel disease
- Osteomyelitis

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients who are very obese, who may exceed the weight limit for the equipment
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Retained barium from a previous radiologic procedure, which may inhibit visualization of an abdominal lesion
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Other nuclear scans done within 48 hours and Ga-67 scans within 4 weeks before the procedure
- Lesions smaller than 1 to 2 cm, which may not be detectable

- A distended bladder, which may obscure pelvic detail

Other considerations:

- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- Patients with a low WBC count may need donor WBCs to complete the radionuclide labeling process; otherwise, Ga-67 scanning should be performed instead.
- False-negative images may be a result of hemodialysis, hyperglycemia, hyperalimentation, steroid therapy, and antibiotic therapy.
- The presence of multiple myeloma or thyroid cancer can result in a false-negative scan for bone abnormalities.
- Consultation with a health care practitioner should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiographic overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the area where the examination is being done should wear badges that reveal their level of exposure to radiation.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the procedure assesses the presence of inflammation or infection.
- Obtain a history of the patient's complaints, including a list of known allergens.
- Obtain a history of the patient's immune system, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related diagnostic tests, refer to the Immune System table.
- Note any recent procedures that can interfere with test results, including barium examinations.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient's current medications.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Explain the purpose of the test and how the procedure is performed. Inform the patient that the procedure is performed in a special nuclear medicine department by a technologist and usually takes approximately 60 minutes, and that delayed images are needed 24 hours later. The patient may leave the department and return later to undergo delayed imaging.
- *Sensitivity to cultural and social issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- Ensure that the patient has removed all external metallic objects (jewelry, etc.) prior to the procedure.
- Patients are given a gown, robe, and foot coverings to wear and instructed to void prior to the procedure.

- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer sedative to a child or to an uncooperative adult, as ordered.
- On the day of the test, draw a 40- to 60-mL sample of blood for an in vitro process of labeling and separating the WBCs from the blood. An injection of radionuclide-labeled autologous WBCs is administered. Delayed views may be taken 4 to 24 hours after the injection.
- If abdominal abscess or infection is suspected, laxatives or enemas may be ordered before delayed imaging.
- Wear gloves during the radionuclide administration and while handling the patient's urine.
- The results are recorded manually, on film, or in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Advise patient to drink increased amounts of fluids for 24 hours to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 48 to 72 hours.
- Instruct the patient to flush the toilet immediately after each voiding following the procedure, and to wash hands meticulously with soap and water after each voiding for 24 hours after the procedure.
- Tell all caregivers to wear gloves when discarding urine for 24 hours after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- A written report of the examination will be completed by a health care practitioner specializing in this branch of medicine. The report will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related diagnostic tests:

- Related diagnostic tests include computed tomography of the spine or pelvis; gallium scan; kidney, ureter, and bladder (KUB) study; magnetic resonance imaging of the spine or pelvis; and ultrasound of the abdomen or pelvis.

ZINC

SYNONYM/ACRONYM: Zn.

SPECIMEN: Serum (1 mL) collected in a trace element–free, royal blue–top tube.

REFERENCE VALUE: (Method: Atomic absorption spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 0.153)
Newborn–6 mo	26–141 µg/dL	4.0–21.6 µmol/L
6–11 mo	29–131 µg/dL	4.5–20.1 µmol/L
1–4 y	31–115 µg/dL	4.8–17.6 µmol/L
4–5 y	48–119 µg/dL	7.4–18.2 µmol/L
6–9 y	48–129 µg/dL	7.3–19.7 µmol/L
10–13 y	25–148 µg/dL	3.9–22.7 µmol/L
14–17 y	46–130 µg/dL	7.1–19.9 µmol/L
Adult	70–120 µg/dL	10.7–18.4 µmol/L

DESCRIPTION & RATIONALE: Zinc is found in all body tissues, but the highest concentrations are found in the eye, bone, and male reproductive organs. Zinc is involved in RNA and DNA synthesis and is essential in the process of tissue repair. It is also required for the formation of collagen and the production of active vitamin A (for the visual pigment rhodopsin). Zinc also functions as a chelating agent to protect the body from lead and cadmium poisoning. Zinc is absorbed from the small intestine. Its absorption and excretion seem to be through the same sites as those for iron and copper. The body does not store zinc as it does copper and iron. Untreated zinc deficiency in infants may result in a condition called acrodermatitis enteropathica. Symptoms include growth retardation, diarrhea, impaired wound healing, and frequent infections. Adolescents and adults with zinc deficiency exhibit similar adverse effects on growth, sexual development, and immune function, as well as altered taste and smell, emotional instability, impaired adaptation to darkness, impaired night vision, tremors, and a bullous, pustular rash over the extremities. ■

INDICATIONS:

- Assist in confirming acrodermatitis enteropathica
- Evaluate nutritional deficiency
- Evaluate possible toxicity
- Monitor replacement therapy in individuals with identified deficiencies
- Monitor therapy of individuals with Wilson's disease

RESULT

Increased in:

- Anemia
- Arteriosclerosis
- Coronary heart disease
- Primary osteosarcoma of the bone

Decreased in:

- Acrodermatitis enteropathica
- Acquired immunodeficiency syndrome

- Acute infections
- Acute stress
- Burns
- Cirrhosis
- Conditions that decrease albumin
- Diabetes
- Long-term total parenteral nutrition
- Malabsorption
- Myocardial infarction
- Nephrotic syndrome
- Nutritional deficiency
- Pregnancy
- Pulmonary tuberculosis

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- Drugs that may increase zinc levels include auranofin, chlorthalidone, corticotropin, oral contraceptives, and penicillamine.
- Drugs that may decrease zinc levels include anticonvulsants, cisplatin, citrates, corticosteroids, estrogens, interferon, and oral contraceptives.

Nursing Implications and Procedure

Pretest:

- Inform the patient that the test is used to evaluate disorders associated with abnormal zinc levels and monitor response to therapy.
- Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex), and inform the appropriate health care practitioner accordingly.
- Obtain a history of the patient's gastrointestinal, hepatobiliary, immune, and musculoskeletal systems, as well as results of previously performed laboratory tests, surgical procedures, and other diagnostic procedures. For related laboratory tests, refer to the Gastrointestinal, Immune, Hepatobiliary, and Musculoskeletal System tables.
- Obtain a list of medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals. The requesting health care practitioner and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain related to the procedure. Explain to the patient that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:

- If the patient has a history of severe allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL royal blue–top tube.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.
- The results are recorded manually or

in a computerized system for recall and postprocedure interpretation by the appropriate health care practitioner.

Post-test:

- Observe venipuncture site for bleeding or hematoma formation. Apply paper tape or other adhesive to hold pressure bandage in place, or replace with a plastic bandage.
- *Nutritional considerations:* Topical or oral supplementation may be ordered for patients with zinc deficiency. Dietary sources high in zinc include shellfish, red meat, wheat germ, and processed foods such as canned pork and beans and canned chili. Patients should be informed that diets high in phytates from whole grains, coffee, cocoa, or tea bind zinc and prevent it from being absorbed. Decreases in zinc also can be induced by increased intake of iron, copper, or manganese. Vitamin and mineral supplements with a greater than 3:1 iron/zinc ratio inhibit zinc absorption.
- A written report of the examination will be sent to the requesting health care practitioner, who will discuss the results with the patient.
- Reinforce information given by the patient's health care provider regarding further testing, treatment, or referral to another health care provider. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related laboratory tests:

- Related laboratory tests include albumin, iron, and copper.

APPENDIX A

Patient Preparation and Specimen Collection

Patient Preparation Before Diagnostic and Laboratory Procedures

The first step in any laboratory or diagnostic procedure is patient preparation or patient teaching before the performance of the procedure. This pretesting explanation to the patient or caregiver follows essentially the same pattern for all sites and types of studies and includes the following:

- *Statement of the purpose of the study.* The level of detail provided to patients about the test purpose depends on numerous factors and should be individualized appropriately in each particular setting.
- *Description of the procedure, including site and method.* It is a good idea to explain to the patient that you will be wearing gloves throughout the procedure. The explanation should help the patient understand that the use of gloves is standard practice established for his or her protection as well as yours. Many institutions require hand washing at the beginning and end of each specimen collection encounter and between each patient.
- *Description of the sensations, including discomfort and pain, that the patient may experience during the specimen collection procedure.* Address concerns about pain related to the procedure and suggest breathing or visualization techniques to promote relaxation. For pediatric patients, a doll may be used to "show" the procedure. Where appropriate, the use of sedative or anesthetizing agents may assist in allaying anxiety the patient may experience that is related to anticipation of pain associated with the procedure. Sensitivity to cultural and social issues, as well as concern for modesty, is important in providing psychological support.
- *Instruction regarding pretesting preparations related to diet, liquids, medications, and activity as well as any restrictions regarding diet, liquids, medications, activity, known allergies, therapies, or other procedures that might affect test results.* To increase patient compliance, the instructions should include an explanation of why strict adherence to the instructions is required.
- *Recognition of anxiety related to test results.* Provide a compassionate, reassuring environment. Be prepared to educate the patient regarding access to the appropriate counseling services. Encourage the patient to ask questions and verbalize his or her concerns.

Specific collection techniques and patient preparation vary by site, study required, and level of invasiveness. These techniques are described in the individual monographs.

Blood Specimens

Most laboratory tests that require a blood specimen use venous blood. Venous blood can be collected directly from the vein or by way of capillary puncture. Capillary blood can be obtained from the fingertips or earlobes of adults and small children. Capillary blood can also be obtained from the heels of infants. The circumstances in which the capillary method would be selected over direct venipuncture include cases in which:

- The patient has poor veins.
- The patient has small veins.
- The patient has a limited number of available veins.
- The patient has significant anxiety about the venipuncture procedure.

Venous blood also can be obtained from vascular access devices, such as heparin locks and central venous catheters. Examples of central venous catheters include the triple-lumen subclavian, Hickman, and Groshong catheters.

Fetal blood samples can be obtained, when warranted, by a qualified health care practitioner from the scalp or from the umbilical cord.

Arterial blood can be collected from the radial, brachial, or femoral artery if blood gas analysis is requested.

There are some general guidelines one should follow in the procurement and handling of blood specimens:

- It is essential that the patient be positively and properly identified. Specimens should always be labeled with the patient's name, medical record number (or some other unique identifier), date collected, time collected, and initials of the person collecting the sample.
- Requisitions should be completed accurately and submitted per laboratory policy.
- The practice of an overnight fast before specimen collection is a general recommendation. Reference ranges are often based on fasting populations to provide some level of standardization for comparison. Some test results are dramatically affected by foods, however, and fasting is a pretest requirement. The presence of lipids in the blood also may interfere with the test method; fasting eliminates this potential source of error, especially if the patient already has elevated lipid levels. The laboratory should always be consulted if there is a question as to whether fasting is a requirement or a recommendation.
- Gloves and any other additional personal protective equipment indicated by the patient's condition should always be worn during the specimen collection process. Appendix G can be consulted for a more detailed description of standard precautions.
- Stress can cause variations in some test results. A sleeping patient should be gently awakened and allowed the opportunity to become oriented before collection site selection. Comatose or unconscious patients should be greeted in the same gentle manner because, although they are unable to respond, they may be capable of hearing and understanding. Anticipate instances in which patient cooperation may be an

issue. Enlist the assistance of a second person to assist with specimen collection to ensure a safe, quality collection experience for all involved.

- Localized activity such as the application of a tourniquet or clenching the hand to assist in visualizing the vein can cause variations in some test results. It is important to be aware of affected studies before specimen collection.
- Hemoconcentration may cause variations in some test results. The tourniquet should never be left in place for longer than 1 minute.
- Previous puncture sites should be avoided when accessing a blood vessel by any means, to reduce the potential for infection.
- Specimens should never be collected above an intravenous (IV) line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. It is also possible that substances in the IV solution could contaminate the specimen and result in falsely elevated test results.
- Changes in posture from supine to erect or long-term maintenance of a supine posture causes variations in some test results. It is important to be aware of this effect when results are interpreted and compared with previous values.
- Collection times for therapeutic drug (peak and trough) or other specific monitoring (e.g., chemotherapy, glucose, insulin, or potassium) should be documented carefully in relation to the time of medication administration. It is essential that this information be communicated clearly and accurately to avoid misunderstanding of the dose time in relation to the collect time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause of subtherapeutic levels, toxic levels, and misleading information used in the calculation of future therapies.
- The laboratory should be consulted regarding minimum specimen collection requirements when multiple tube types or samples are required. The amount of serum or plasma collected can be estimated using assumptions of packed cell volume or hematocrit. The packed cell volume of a healthy woman is usually 38% to 44% of the total blood volume. If a full 5-mL red-top tube is collected, and the hematocrit is 38% to 44%, approximately 2.8 to 3.1 mL, or [5 – (5 (0.44)] to [5 – (5 × 0.38)], of the total blood volume should be serum. Factors that invalidate estimation include conditions such as anemia, polcythemia, dehydration, or overhydration.
- The laboratory should be consulted regarding the preferred specimen container before specimen collection. Specific analytes may vary in concentration depending on whether the sample is serum or plasma. It is recommended that, when serial measurements are to be carried out, the same type of collection container be used so that fluctuations in values caused by variations in specimen type are not misinterpreted as changes in clinical status. Consultation regarding collection containers is also important because some laboratory methods are optimized for a specific specimen type (serum versus plasma). Also, preservatives present in collection containers, such as sodium fluoride, may exhibit a chemical interference with test reagents that can cause underestimation or overestimation of measured values. Other preservatives, such as ethylenediaminetetra-acetic acid (EDTA), can block the analyte of interest in the sample from participating in the test reaction, invalidating test results. Finally, it is possible that some high-throughput, robotic equipment systems require specific and standardized collection containers.

- Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results. Specimens collected in containers with solid or liquid preservatives or with gel separators should be mixed by inverting the tube 10 times immediately after the tube has been filled. Handle the specimen gently to avoid hemolysis. Specimens should always be transported to the laboratory as quickly as possible after collection.

Results that are evaluated outside the entire context of the preparatory, collection, and handling process may be interpreted erroneously if consideration is not given to the above-listed general guidelines.

Site Selection

Capillary Puncture: Assess the selected area. It should be free of lesions and calluses, there should be no edema, and the site should feel warm. If the site feels cool or if the site appears pale or cyanotic, warm compresses can be applied over 3 to 5 minutes to dilate the capillaries. For finger sticks, the central, fleshy, distal portions of the third or fourth fingers are the preferred collection sites (Figure Appenix A–1). For neonatal heel sticks, the medial and lateral surfaces of the plantar area are preferred to avoid direct puncture of the heel bone, which could result in osteomyelitis (Figure Appenix A–2).

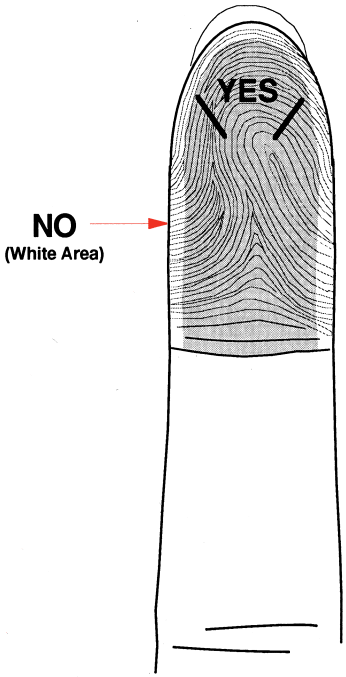

FIGURE A–1 Site selection. Capillary puncture of the finger.

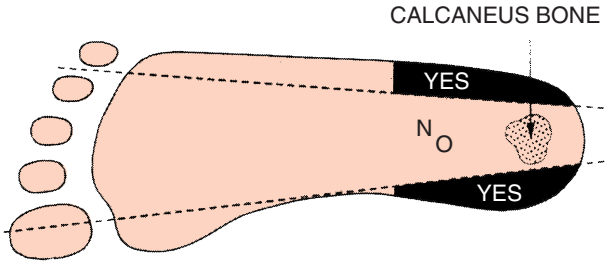

FIGURE A–2 Site selection. Capillary puncture of the heel.

Venipuncture of Arm: Assess the arm for visibly accessible veins. The selected area should not be burned or scarred, have a tattoo, or have hematoma present. Even after the tourniquet is applied, not all patients have a prominent median cubital, cephalic, or basilic vein. Both arms should be observed because some patients have accessible veins in one arm and not the other. The median cubital vein in the antecubital fossa is the preferred venipuncture site. The patient may be able to provide the best information regarding venous access if he or she has had previous venipuncture experience (Figure Appendix A–3). Alternative techniques to increase visibility of veins may include warming the arm, allowing the arm to dangle downward for a minute or two, tapping the antecubital area with the index finger, or massaging the arm upward from wrist to elbow. The condition of the vein also should be assessed before venipuncture. Sclerotic (hard, scarred) veins or veins in which phlebitis previously occurred should be avoided. Arms with a functioning hemodialysis access site should not be used. The arm on the affected side of a mastectomy should be avoided. In the case of a double mastectomy, the requesting health care practitioner should be consulted before specimen collection.

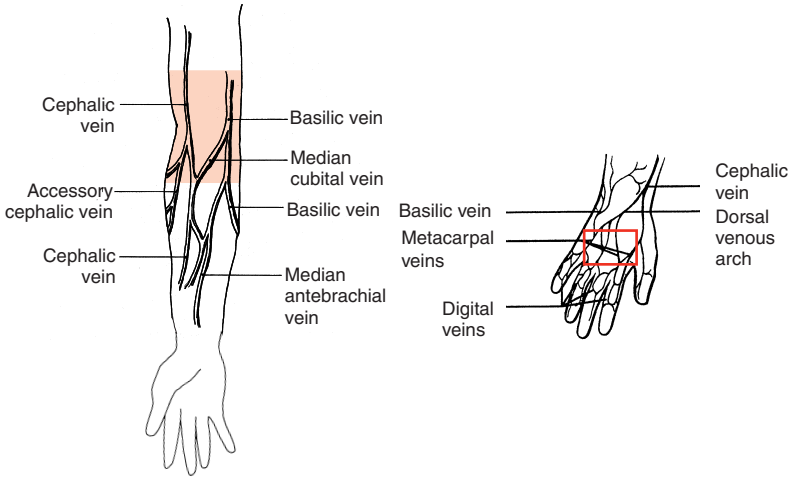

FIGURE A–3 Site selection. Venipuncture arm/hand.

Venipuncture of Hand and Wrist: If no veins in the arms are available, hands and wrists should be examined as described previously. Consideration should be given to the venipuncture equipment selected because the veins in these areas are much smaller. Pediatric-sized collection containers and needles with a larger gauge may be more appropriate.

Venipuncture of Legs and Feet: The veins in the legs and feet can be accessed as with sites located on the arm, hand, or wrist. These extremities should be used only on the approval of the requesting health care practitioner because veins in these locations are more prone to infection and formation of blood clots, especially in patients with diabetes, cardiac disease, and bleeding disorders.

Radial Arterial Puncture: The radial artery is the artery of choice for obtaining arterial blood gas specimens because it is close to the surface of the wrist and does not require a deep puncture. Its easy access also allows for more effective compression after the needle has been removed. The nearby ulnar artery can provide sufficient collateral circulation to the hand during specimen collection and postcollection compression (Figure Appendix A–4).

Percutaneous Umbilical Cord Sampling: The blood is aspirated from the umbilical cord under the guidance of ultrasonography and using a 20- or 22-gauge spinal needle inserted through the mother's abdomen.

Postnatal Umbilical Cord Sampling: The blood is aspirated from the umbilical cord using a 20- or 22-gauge needle and transferred to the appropriate collection container.

Fetal Scalp Sampling: The requesting health care practitioner makes a puncture in the fetal scalp using a microblade, and the specimen is collected in a long capillary tube. The tube is usually capped on both ends immediately after specimen collection.

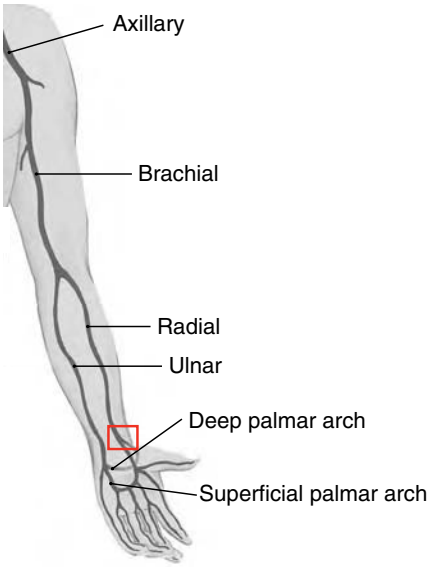

FIGURE A–4 Site selection. Arterial arm/hand.

Locks and Catheters: These devices are sometimes inserted to provide a means for the administration of fluids or medications and to obtain blood specimens without the need for frequent venipuncture. The device first should be assessed for patency. The need for heparinization, irrigation, or clot removal depends on the type of device in use and the institution-specific or health care practitioner–specific protocols in use. Care should be taken to use sterile technique because these devices provide direct access to the patient's bloodstream. When IV fluids are being administered via a device at the time of specimen collection, blood should be obtained from the opposite side of the body. If this is not possible, the flow should be stopped for 5 minutes before specimen collection. The first 5 mL of blood collected should be discarded.

Selection of Blood Collection Equipment

In many cases when a blood sample is required, serum is the specimen type of choice. Plasma may be frequently substituted, however. Specimen processing is more rapid for plasma samples than serum samples because the anticoagulated sample does not need to clot before centrifugation. Plasma samples also require less centrifugation time to achieve adequate separation. Consult with the testing laboratory regarding recommended specimen types. The basic blood collection tubes are shown on the inside cover of this book. Consider latex allergy when selecting the collection equipment appropriate for each patient. Equipment used in specimen collection includes:

- Gloves and other personal protective equipment depending on the situation
- Tourniquet
- Materials to cleanse or disinfect the collection site (alcohol preparations [70% alcohol], povidone-iodine solution [Betadine], or green soap are the most commonly used materials)
- Gauze (to wipe collection site dry after cleansing)
- Sterile lancet (capillary puncture)
- Syringe and needle (arterial puncture or venipuncture)
- Vial of heparin and syringe or heparin unit dose
- Sterile normal saline in 50-mL syringe (for indwelling devices such as Groshong catheter)
- Sterile cap or hub (for indwelling devices when the cap or hub will be replaced after specimen procurement)
- Needle and holder for vacuumized collection tube system (arterial puncture or venipuncture)
- Butterfly or winged infusion set (venipuncture)
- Collection container (vacuumized collection tube, capillary tube, or Microtainer)
- Bandage (to cover puncture site after specimen collection)

Collection Procedure

The procedures outlined here are basic in description. A phlebotomy or other text should be consulted for specific details regarding specimen collection and complications encountered during various types of blood collection.

Capillary: Place the patient in a comfortable position either sitting or lying down. Assess whether the patient has allergies to the disinfectant or to latex if latex gloves or

tourniquet will be used in the collection procedure. Use gloved hands to select the collection site as described in the site selection section. Cleanse the skin with the appropriate disinfectant and dry the area. Pull the skin tight by the thumb and index finger of the nondominant hand on either side of the puncture site and moving them in opposite directions. Puncture the skin with a sterile lancet to a depth of approximately 2 mm, using a quick, firm motion. Wipe the first drop of blood away using the gauze. If flow is poor, the site should not be squeezed or the specimen may become contaminated with tissue fluid. Do not allow the collection container to touch the puncture site. Collect the sample in the capillary tube or Microtainer. The capillary tube should be held in a horizontal position to avoid the introduction of air bubbles into the sample. Microtainer tubes should be held in a downward-slanted direction to facilitate the flow of blood into the capillary scoop of the collection device. If a smear is required, allow a drop of blood to fall onto a clean microscope slide. Gently spread the drop across the slide using the edge of another slide. Apply slight pressure to the puncture site with a clean piece of gauze until bleeding stops, and then apply a bandage. Safely dispose of the sharps. Properly label the specimens and transport immediately to the laboratory.

Venipuncture Using a Syringe or Vacuumized Needle and Holder System: Place the patient in a comfortable position either sitting or lying down. Assess whether the patient has allergies to the disinfectant or to latex if latex gloves or tourniquet will be used in the collection procedure. Use gloved hands to select the collection site as described in the site selection section. Locate the vein visually, then by palpation using the index finger. The thumb should not be used because it has a pulse beat and may cause confusion in site selection or in differentiating a vein from an artery. Select the appropriate collection materials (needle size, butterfly, syringe, collection container size) based on the vein size, vein depth, appearance of the collection site, patient's age, and anticipated level of cooperation. Cleanse the skin with the appropriate disinfectant and dry the area. Select the appropriate collection tubes. If blood cultures are to be collected, disinfect the top of the collection containers as directed by the testing laboratory. Be sure to have extra tubes within easy reach in case the vacuum in a collection tube is lost and a substitute is required. Apply the tourniquet 3 to 4 inches above the selected collection site. Remove the sterile needle cap, and inspect the tip of the needle for defects. Pull the skin tight by placing the thumb of the nondominant hand 1 or 2 inches below the puncture site and moving the thumb in the opposite direction. The thumb is placed below the puncture site to help avoid an accidental needle stick if the patient should suddenly move. Ensure that the needle is bevel up and held at an angle of approximately 15° to 30° (depending on the depth of the vein) (Figure Appendix A–5).

Puncture the skin with smooth, firm motion using a sterile needle held by the dominant hand. A reduction in pressure is achieved when the needle has penetrated the vein successfully. Be sure to release the tourniquet within 1 minute of application. Fill the vacuumized collection containers in the prescribed order of draw for the studies ordered. Tubes with anticoagulants can be gently mixed with the free nondominant hand as they are filled. When the required containers have been filled, withdraw the needle and apply pressure to the collection site until the bleeding stops. In most cases, a piece of gauze can be placed on the collection site and the arm bent upward to hold

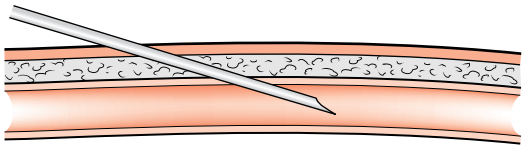

FIGURE A–5 Venipuncture needle placement at insertion.

it in place while attention is given to disposing of the sharps safely and labeling the collection tubes properly. In cases in which a syringe is used, the barrel of the syringe should be gently pulled back during specimen collection and gently pushed in during the transfer to collection tubes. The vacuum in the collection container should not be allowed to suck the sample into the container, but rather the speed of entry should be controlled by the pressure applied to the barrel. The blood should gently roll down the side of the tube to prevent hemolysis.

Radial Artery Puncture: Place the patient in a comfortable position either sitting or lying down. Assess whether the patient has allergies to the disinfectant or to latex if latex gloves or tourniquet will be used in the collection procedure. Assess if the patient has an allergy to local anesthetics, and inform the health care practitioner accordingly. Glove the hands, and select the collection site as described in the site selection section. Ensure that the patient has adequate collateral circulation to the hand if thrombosis of the radial artery occurs after arterial puncture by performing an Allen test before puncture. The Allen test is performed by occlusion of the ulnar and radial arteries on the palmar surface of the wrist with two fingers. The thumb should not be used to locate these arteries because it has a pulse. Compress both arteries, and ask the patient to open and close the fist several times until the palm turns pale. Release pressure only on the ulnar artery. Color should return to the palm within 5 seconds if the ulnar artery is functioning. If coloring returns above the wrist, the Allen test is positive. The Allen test also should be performed on the opposite hand. The wrist to which color is restored fastest has better circulation and should be selected as the site for blood gas collection. Be sure to explain to the patient that an arterial puncture is painful. The site may be anesthetized with 1% to 2% lidocaine (Xylocaine) before puncture. The index finger of the nondominant hand is placed over the site where the needle will enter the artery, not the site where the needle will penetrate the skin. The specimen is collected in an air-free heparinized syringe, which is held like a dart in the dominant hand and inserted slowly, bevel up, about 5 to 10 mm below the palpating finger at a 45° to 60° angle. When blood enters the needle hub, arterial pressure should cause blood to pump into the syringe. When enough specimen has been collected, the needle is withdrawn from the arm, and pressure is applied to the collection site for a minimum of 5 to 10 minutes. Immediately after the needle has been withdrawn safely from the arm, the exposed end of the syringe should be stoppered.

Samples should be gently and well mixed to ensure proper mixing of the heparin with the sample. The heparin prevents formation of small clots that result in rejection of the sample. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label can be protected from water in the ice slurry if the specimen is first placed in a protective plastic bag.

Indwelling Devices: Indwelling devices are either heparinized or irrigated after specimen collection. Before specimen collection, prepare the heparin in a syringe, if required. Allow the heparin (unit dose or prepared solution in the syringe) to equilibrate at room temperature during specimen collection. Cleanse the catheter cap or hub with povidone-iodine and 70% alcohol over 2 minutes. Using sterile gloves, remove the cap and attach a 5- or 10-mL syringe to the connector. Withdraw 5 mL of blood to be discarded. Clamp the catheter. (The Groshong catheter does not require clamping because it has a special valve that eliminates the need for clamping.) Attach another 5- or 10-mL syringe and begin collecting blood for transfer to the collection tubes. After the required specimen has been withdrawn, the device is heparinized by slowly injecting the heparin into the cap or hub of the device. Clamp the device 2 inches from the cap, remove the needle, and unclamp the device. Attach a new sterile cap or hub if the old one has been discarded. Groshong catheters are irrigated rather than heparinized. Irrigation of a Groshong catheter is accomplished by gently injecting 20 to 30 mL of sterile normal saline through the cap with moderate force. Remove the needle using some positive pressure (pressing down on the plunger) to prevent the solution from backing up into the syringe.

Order of Draw for Glass or Plastic Tubes (Reflects 2004 change in CLSI [formerly NCCLS] guideline: Recommended Order of Draw, H3-A5, [Vol 23, No 32, 8.10.2])

Note: Always follow your facility's protocol for order of draw.

- First—Blood culture and other tests requiring sterile specimen (yellow or yellow/black stopper); blood culture bottle first, followed by sodium polyethanol sulfonate (SPS) tube for acid-fast bacilli specimens.
- Second—Coagulation studies (light blue [sodium citrate] stopper); sodium citrate forms calcium salts to remove calcium, and this prevents specimen clotting. *Note:* When using a winged blood collection set and the blue-top tube is the first tube drawn, a nonadditive red-top or coagulation discard tube should be collected first and discarded. The amount of blood in the discard tube needs to be sufficient to fill the winged collection set tubing's "dead space." This is done to eliminate contamination of the specimen with tissue thromboplastin and to ensure the proper ratio of blood to additive in the test specimen blue-top tube.
- Third—Plain or nonadditive (red or red/gray (gel) stopper); red/gray-top serum separator tube (SST) contains a gel separator and clot activator. SSTs are not appropriate for all testing requiring a serum specimen. They are generally unacceptable for therapeutic drug monitoring and serology studies. The laboratory should be consulted if there are questions regarding the use of SSTs.
- Last—Additive tubes in the following order:

Green stopper; tube contains sodium heparin or lithium heparin anticoagulant (heparin inactivates thrombin and thromboplastin, and this prevents specimen clotting). For ammonia levels, use sodium or lithium heparin. For lithium levels, use sodium heparin.

Lavender stopper; tube contains Kt_3 EDTA (tri-potassium EDTA forms calcium salts to remove calcium from the sample, and this prevents specimen clotting while preserving the integrity of the red blood cell wall).

Gray stopper; tube contains potassium oxalate/sodium fluoride (the potassium oxalate acts as an anticoagulant, and the sodium fluoride prevents glycolysis).

Urine Specimens

The patient should be informed that improper collection, storage, and transport are the primary reasons for specimen rejection and subsequent requests for recollection. If the specimen is to be collected at home, it should be collected in a clean plastic container (preferably a container from the testing laboratory). Many studies require refrigeration after collection. If the collection container includes a preservative, the patient should be made aware of the contents and advised as to what the precaution labels mean (caution labels such as caustic, corrosive, acid, and base should be affixed to the container as appropriate). When a preservative or fixative is included in the container, the patient should be advised not to remove it. The patient also should be told not to void directly into the container. The patient should be given a collection device, if indicated, and instructed to void into the collection device. The specimen should be carefully transferred into the collection container. Some laboratories provide preprinted collection instructions tailored to their methods. The specimen should be transported promptly to the laboratory after collection.

Wear gloves and any other additional personal protective equipment indicated by the patient's condition. See Appendix F for a more detailed description of standard precautions. Assess whether the patient has allergies to the disinfectant or anesthetic, or to latex if latex gloves or catheter will be used in the procedure.

Random: These samples are mainly used for routine screening and can be collected at any time of the day. The patient should be instructed to void either directly into the collection container (if there is no preservative) or into a collection device for transfer into the specimen container.

First Morning: Urine on rising in the morning is very concentrated. These specimens are indicated when screening for substances that may not be detectable in a more dilute random sample. These specimens are also necessary for testing conditions such as orthostatic proteinuria, in which levels vary with changes in posture.

Second Voided: In some cases, it is desirable to test freshly produced urine to evaluate the patient's current status, as with glucose and ketones. Explain to the patient that he or she should first void and then drink a glass of water. The patient should be instructed to wait 30 minutes and then void either directly into the collection container or into a collection device for transfer into the collection container.

Clean Catch: These midstream specimens are generally used for microbiologic or cytologic studies. They also may be requested for routine urinalysis to provide a specimen that is least contaminated with urethral cells, microorganisms, mucus, or other substances that may affect the interpretation of results. Instruct the male patient first to wash hands thoroughly, then cleanse the meatus, void a small amount into the toilet, and void either directly into the specimen container or into a collection device for transfer into the specimen container. Instruct the female patient first to wash hands thoroughly, and then to cleanse the labia from front to back. While keeping the labia separated, the patient should void a small amount into the toilet, and then, without interrupting the urine stream, void either directly into the specimen container or into a collection device for transfer into the specimen container.

Catheterized Random or Clean Catch: "Straight catheterization" is indicated when the patient is unable to void, when the patient is unable to prepare properly for clean-catch specimen collection, or when the patient has an indwelling catheter in place from which a urine sample may be obtained. Before collecting a specimen from the catheter, observe the drainage tube to ensure that it is empty, and then clamp the tube distal to the collection port 15 minutes before specimen collection. Cleanse the port with an antiseptic swab such as 70% alcohol and allow the port to dry. Use a needle and syringe (sterile if indicated) to withdraw the required amount of specimen. Unclamp the tube.
Timed: To quantify substances in urine, 24-hour urine collections are used. They are also used to measure substances whose level of excretion varies over time. The use of preservatives and the handling of specimens during the timed collection may be subject to variability among laboratories. The testing laboratory should be consulted regarding specific instructions before starting the test. Many times the specimen must be refrigerated or kept on ice throughout the entire collection period. Explain to the patient that it is crucial for *all* urine to be included in the collection. The test should begin between 6 and 8 a.m., if possible. Instruct the patient to collect the first void of the day and discard it. The start time of the collection period begins at the time the first voided specimen was discarded and should be recorded along with the date on the collection container. The patient should be instructed to void at the same time the following morning and to add this last voiding to the container. This is the end time of the collection and should be recorded along with the date on the container. For patients who are in the hospital, the urinary output should be compared with the volume measured in the completed collection container. Discrepancies between the two volumes indicate that a collection might have been discarded. Many times a creatinine level is requested along with the study of interest to evaluate the completeness of the collection.
Catheterized Timed: Instructions for this type of collection are basically the same as those for timed specimen collection. The test should begin by changing the tubing and drainage bag. If a preservative is required, it can be placed directly in the drainage bag, or the specimen can be removed at frequent intervals (every 2 hours) and transferred to the collection container to which the preservative has been added. The drainage bag must be kept on ice or emptied periodically into the collection container during the entire collection period if indicated by the testing laboratory. The tubing should be monitored throughout the collection period to ensure continued drainage.
Suprapubic Aspiration: This procedure is performed by inserting a needle directly into the bladder. Because the bladder is normally sterile, the urine collected should also be free from any contamination caused by the presence of microorganisms. Place the patient in a supine position. Cleanse the area with antiseptic and drape with sterile drapes. A local anesthetic may be administered before insertion of the needle. A needle is inserted through the skin into the bladder. A syringe attached to the needle is used to aspirate the urine sample. The needle is then removed and a sterile dressing is applied to the site. Place the sterile sample in a sterile specimen container. The site must be observed for signs of inflammation or infection.
Pediatric: Specimen collection can be achieved by any of the above-described methods using collection devices specifically designed for pediatric patients. Appropriately cleanse the genital area and allow the area to dry. For a random collection, remove the covering of the adhesive strips on the collector bag and apply over the genital area.

Diaper the child. When the specimen is obtained, place the entire collection bag in the specimen container (use a sterile container as appropriate for the requested study). Some laboratories may have specific preferences for the submission of urine specimens for culture. Consult the laboratory before collection to avoid specimen rejection.

Body Fluid, Stool, and Tissue

Wear gloves and any other additional personal protective equipment indicated by the patient's condition. See Appendix G for a more detailed description of standard precautions. Assess whether the patient has allergies to the disinfectant or anesthetic, or to latex if latex gloves will be used in the procedure.

Specific collection techniques vary by site, study required, and level of invasiveness. These techniques are described in the individual monographs.

Diagnostic Testing

Wear gloves and any other additional personal protective equipment indicated by the patient's condition. See Appendix G for a more detailed description of standard precautions. Assess whether the patient has allergies to the disinfectant, anesthetic, contrast material, or medications, or to latex if latex gloves, catheter, or tourniquet will be used in the procedure.

A sleeping patient should be gently awakened and allowed the opportunity to become oriented before preparation for the selected study. Comatose or unconscious patients should be greeted in the same gentle manner because, although they are unable to respond, they may be capable of hearing and understanding. Anticipate instances in which patient cooperation may be an issue. Enlist the assistance of a second person to help with preparing the patient for the procedure to ensure a safe, quality testing experience for all involved.

Specific techniques and patient preparation vary by site, study required, and level of invasiveness. These techniques are described in the individual monographs.

APPENDIX B

Potential Nursing Diagnoses Associated with Laboratory and Diagnostic Testing

Pretest Phase

Anxiety related to undiagnosed health problems
Anxiety related to perceived threat to health status
Anxiety and fear related to anticipated diagnostic results
Anxiety and fear related to perception of diagnostic procedure as frightening or embarrassing
Powerlessness related to unfamiliar procedure, equipment, environment, or personnel
Knowledge deficit related to lack of information or possible misinterpretation of information provided about the procedure
Knowledge deficit related to legal implications of testing
Potential for noncompliance with test protocols related to inability to understand or follow instructions
Potential for noncompliance with test protocols related to presence of high anxiety, confusion, or denial
Potential for noncompliance with test protocols related to lack of knowledge or appropriate instruction
Potential for noncompliance with test protocols related to confusion, weakness, and other individual factors

Intratest Phase

Risk for injury related to developmental age, psychological factors, and test procedures
Risk for infection or allergic reaction related to altered immune function, history of chronic illness, allergens, or infectious agent
Risk for latex allergy response associated with test equipment
Pain, nausea, vomiting, or diarrhea related to laboratory and diagnostic procedures
Injury, actual or risk for, related to invasive procedure associated with laboratory or diagnostic testing
Risk for infection related to invasive procedures
Risk for bleeding associated with altered bleeding tendencies related to invasive procedures
Fatigue related to diagnostic procedure
Anxiety and fear related to arterial puncture or venipuncture
Risk for injury, bleeding, hematoma, or infection related to arterial puncture or venipuncture
Pain related to arterial puncture or venipuncture
Risk for impaired skin integrity

Potential impairment of gas exchange associated with test procedure

Post-Test Phase

Knowledge deficit related to significance of test results and potential need for further testing

Knowledge deficit related to test outcome deviation that may necessitate medication or lifestyle alterations

Anxiety and fear related to test outcome deviation that may necessitate medication or lifestyle alterations

Ineffective coping related to test outcome and potential for other interventional techniques or procedures

Anticipatory grieving related to test outcomes

Anticipatory or actual grieving related to perceived loss of health or threat of death associated with diagnostic outcomes

Decisional conflict related to test outcome and potential for interventional procedures

Potential alteration in tissue perfusion: cerebral, cardiopulmonary, or peripheral

Knowledge deficit related to care after procedure

APPENDIX C

Guidelines for Age-Specific Communication

Effective communication between the health care practitioner and the patient is influenced by the patient's cognitive abilities, sensory development or deprivation, level of stress, and environment. Effective communication with individuals at any stage of life is possible if one recognizes that it is essential to employ age-specific communication techniques based on an understanding of the continuum of human development as highlighted here.

Infant (Birth to 1 year)

Physical

Rapid gains in height and weight
Gradual shift from reflexive movements to intentional actions

Motor and Sensory

Responds to light and sound
Progresses to raising and turning head, bringing hand to mouth, rolling over, sitting upright, and standing

Cognitive

Learns by imitation
Progresses to recognize familiar objects and people
Advances to speaking three or four words

Psychosocial

Significant persons are parents or primary caregivers
Develops sense of trust and security if needs are met
May show fear of strangers
May exhibit separation anxiety

Interventions

Keep a parent or primary caregiver in view
Involve significant persons in care if appropriate
Provide consistency in health care staff to limit the number of strangers
Face the infant when providing care
Use soothing nonverbal communication, such as holding, rocking, and cuddling
Assess immunizations
Maintain safety and keep crib side rails up at all times

Toddler (1 to 4 years)

Physical

Learning bladder and bowel control
Temporary teeth erupt
Physiologic systems mature

Motor and Sensory

Developing a higher level of manual dexterity (builds towers with blocks)
Progresses to walking, jumping, and climbing
Loves to experiment

Cognitive

Has a short attention span
Understands simple directions and requests

Psychosocial

Significant persons are parents
Asserts independence
Understands ownership
Attached to security objects
Knows own gender
Plays simple games

Interventions

Face the toddler during interactions
Give one direction at a time
Tie words to action (toddlers learn by example)
Use firm, direct approach; avoid harsh/excited words or actions
Use distraction techniques
Use soothing nonverbal communication, such as rocking, cuddling, and holding
Communicate through play (dolls, puppets, music)
Prepare shortly before a procedure
Allow choices when possible
Encourage mother or parent to stay with the child as appropriate
Encourage parents to participate in care as appropriate
Maintain safety and keep crib side rails up at all times

Child (5 to 12 years)

Physical

Growth is slow and regular
Permanent teeth erupt
Pubescent changes start
May experience growing pains
May experience fatigue

Motor and Sensory

Skips and hops
Dresses and undresses independently
Throws and catches a ball
Uses common utensils and tools
Draws, paints, and likes quiet as well as active games

Cognitive

Major cognitive skill is communication
Understands numbers and can count
Constructs sentences and asks questions
Capable of logical thinking and can reason
Takes pride in accomplishments
Develops increased attention span

Psychosocial

Significant persons are parents, siblings, peers, teachers (prefers friends to family)
Increases independence and begins to assert self (may be physically aggressive)
Masters new tasks and acquires new skills
Behavior can be modified by rewards and punishment
Works hard to be successful

Interventions

Clearly define and reinforce behavior limits
Tell jokes and play games with rules

Check for special words used to identify parents, body parts, or body functions
Explain procedures in advance using correct terminology
Use dolls or puppets for explanations when performing procedures
Provide privacy
Involve whenever possible
Allow to have some control
Promote independence
Praise for good behavior
Acknowledge fear, pain, or family separation

Adolescent (13 to 18 years)

Physical

Growth in skeletal size is rapid
Reproductive system matures
Vital signs approximate those of an adult

Motor and Sensory

Easily fatigued
May need more rest and sleep in early adolescence
Awkwardness in gross motor activity
Demonstrates improving fine motor skills

Cognitive

Increased ability to use abstract thought and logic
Able to handle hypothetical situations and thoughts
Shows growth in self-esteem but is challenged by bouts of insecurity
Avoids asking questions for fear of appearing unintelligent

Psychosocial

Develops sexual identity
Shows interest in and confusion with own development
Develops concern with physical appearance
Establishes critical need for privacy
Values belonging to peer group
Perceives self as invincible
Identity is threatened by hospitalization

Interventions

Likes to be treated like an adult
Do not talk to others about the patient in front of him or her
Do not ask questions about drugs, sex, or use of tobacco in front of parents
Provide information about routines and therapy
Provide privacy
Supplement information with rationale
Encourage questions
Allow to maintain control
Involve in decision making and care
Allow for expression of fear, such as fear of bodily injury and loss of control

Adult (19 to 65 years)

Physical

Reaches physical and sexual maturity
Prone to health problems related to an inability to cope with new responsibilities
Health care needs related to preventive medicine
Adjustment to menopause (women) and sexual dysfunction (men) in middle adulthood

Motor and Sensory

Skills are fully developed

Cognitive

Focuses on time constraints and want to learn only what is practical for him or her
May be dual caregivers (i.e., parents and children)

Psychosocial

Experiences emotional stress secondary to mate selection, vocational selection, assuming occupational roles, marriage, childbearing, financial pressure, and independence

Interventions

Involve family in patient's care and education
Explain benefits of adhering to treatment plan
Be honest and supportive
Respect personal values
Provide privacy
Keep a hopeful attitude
Focus on strengths, and not limitations
Recognize that unknown factors may affect behavior
Encourage patient to ask questions and talk about concerns
Provide information and support to make health care decisions

Geriatric (65 and older)

Physical

Ages gradually and individually
Experiences decreased tolerance to heat/cold
Encounters declining cardiac and renal function
Experiences skeletal changes (bones become more prominent, shrinkage in vertebral disks, stiff joints)
Becomes subject to increased susceptibility to infection and to high blood pressure
Undergoes skin changes

Motor and Sensory

Experiences decrease in mobility, visual acuity, ability to respond to stimuli, hearing, and motor skills

Cognitive

Experiences decrease in memory, slowing of mental functions, slowness in learning, and drop in performance

Psychosocial

Encounters lifestyle changes secondary to children leaving home, children providing grandchildren, re-establishing a relationship as a couple, and retirement/hobbies
Develops increased concern for health and financial security
Accepts concept of own mortality
Faces decreased authority and autonomy
Experiences depression related to decreased physical, motor, and cognitive abilities

Interventions

Explain instructions well to patient and family
Ask questions to verify understanding
Review important points repeatedly
Keep room clutter-free and call bell within reach
Control room temperature for comfort
Consider additional lighting at night
Watch for signs of drug toxicity
Give respect and provide privacy
Focus on strengths and not limitations
Avoid assuming loss of abilities
Seek information as necessary to deal with impairments
Include patient in conversation/activity to prevent social isolation
Encourage to talk about feelings
Use humor and stay positive
Provide information and support regarding end-of-life decisions
Provide teaching for safety
Provide teaching for medications and test preparations

APPENDIX D

Transfusion Reactions: Laboratory Findings and Potential Nursing Interventions

These reactions are mainly associated with the transfusion of packed red blood cells.

Categories:

I. Acute (Less than 24 h) Immune-Mediated Transfusion Reactions
   a. ABO and non-ABO acute hemolytic
   b. Febrile nonhemolytic
   c. Urticarial/allergic reaction
   d. Anaphylactic reaction

II. Acute (Less than 24 h) Non–Immune-Mediated Transfusion Reactions
   a. Transfusion-related acute lung injury
   b. Circulatory overload
   c. Metabolic complications
   d. Hypothermia
   e. Hypotension associated with angiotensin-converting enzyme inhibition
   f. Embolism (air and particulate)
   g. Nonimmune hemolysis

III. Delayed (Greater than 24 h) Immune-Mediated Transfusion Reactions
   a. Hemolytic
   b. Alloimmunization to red blood cell, white blood cell, platelet, and protein antigens
   c. Graft versus host

IV. Delayed (Greater than 24 h) Non–Immune-Mediated Transfusion Reactions
   a. Iron overload

I. Acute Immune-Mediated Transfusion Reactions	
a. ABO and non-ABO acute hemolytic	Dramatic, severe, and can be fatal; incidence 1:38,000 to 1:70,000 units; result of reaction between antibodies in the patient's plasma and the corresponding antigen being present on the donor's cells; severity affected by amount of patient antibody present, quantity of antigen on transfused cells, volume of blood transfused
Symptoms	Fever, chills, hypotension, tachycardia, nausea, vomiting, lower back pain, hemoglobinuria, renal failure with oliguria, flushing, generalized bleeding, pain or oozing at the infusion site
Lab Findings	Positive DAT; elevated: indirect bilirubin (5 to 7 h post-transfusion), LDH, BUN, creatinine, PT, PTT; decreased: anti-A and anti-B titers, haptoglobin; hemoglobinemia; hemoglobinuria; hypofibrinogenemia; thrombocytopenia; positive urinary hemosiderin; presence of spherocytes and RBC fragments on peripheral smear
Treatment	Immediately stop transfusion, maintain renal flow at greater than 100 mL/h by use of osmotic and diuretic agents (e.g., lasix, furosemide); monitor for development of DIC (uncontrolled bleeding, decreasing platelet count, prolonged PT/PTT); future transfusion with O-negative packed cells
b. Febrile nonhemolytic	Most common type of transfusion reaction; incidence 1:200 to 1:17 (0.5% to 6.0%); repeat occurrences are uncommon; result of antileukocyte, antiplatelet, or anti-HLA antibodies
Symptoms	Fever, chills, headache, vomiting
Lab Findings	Negative DAT; transient leukopenia
Treatment	Immediately stop transfusion; administer antipyretics (steroids in severe cases); transfuse with leukocyte-reduced blood after two documented febrile nonhemolytic reactions
c. Urticarial/allergic reaction	Second most common type of reaction; incidence 1:100 to 1:33 (1% to 3%); histamine-mediated reaction of allergin + IgE fixed on mast cells
Symptoms	Local erythema; hives; itching; usually no fever
Lab Findings	Negative DAT
Treatment	Immediately stop transfusion; keep line open; administer antihistamines (e.g., benadryl 25 to 50 mg); resume transfusion when symptoms subside; for future transfusions, premedicate with antihistamines

(*Continued on the following page*)

I. Acute Immune-Mediated Transfusion Reactions *(Continued)*	
d. Anaphylactic reaction	Occurs rapidly with 10 mL or less; 1 in 700 individuals are IgA deficient and 25% have anti-IgA antibodies that will react to donor's plasma proteins; incidence 1:20,000 to 1:50,000
Symptoms	Hypotension, urticaria, flushing, substernal pain, abdominal cramping, laryngeal edema, bronchospasm, circulatory collapse, anxiety
Lab Findings	Negative DAT; presence of IgG class anti-IgA antibodies or undetectable level of IgA
Treatment	Treat for anaphylaxis with epinephrine, steroid therapy as needed; oxygen therapy as needed; Trendelenburg position; fluids; for future transfusions, premedicate with antihistamines and transfuse with IgA-deficient donor blood or autologous blood
II. Acute Non–Immune-Mediated Transfusion Reactions	
a. Transfusion-related acute lung injury	Reaction to anti-WBC antibodies in donor unit; incidence 1:5000 to 1:190,000
Symptoms	Hypoxemia, respiratory failure, hypotension, fever
Lab Findings	Positive WBC antibody screen (donor or recipient), incompatible WBC crossmatch
Treatment	Supportive care until recovered; defer implicated donors
b. Circulatory overload	Incidence less than 1%; result of volume overload
Symptoms	Dyspnea, orthopnea, cough, tachycardia, hypertension, headache
Lab Findings	N/A
Treatment	Upright posture; oxygen; diuretic; administer blood slowly; phlebotomy (250-mL increments)
c. Metabolic complications	Hypocalcemia resulting from rapid massive infusion of citrate; incidence dependent on clinical setting
Symptoms	Paresthesia, tetany, arrhythmia
Lab Findings	Elevated ionized calcium level, prolonged Q-T interval on EKG
Treatment	Slow calcium infusion, PO calcium supplement for mild symptoms; monitor ionized calcium levels (severe symptoms)
d. Hypothermia	Result of rapid infusion of cold blood
Symptoms	Cardiac arrhythmia
Lab Findings	N/A
Treatment	Utilize blood warmer

e. Hypotension associated with ACE inhibition	Patients on ACE inhibitors receiving leukocyte-reduced packed cells have experienced hypotension (believed to be the result of an interaction between the ACE inhibitor and the kinin/prekallikrein system); incidence is dependent on the clinical setting.
Symptoms	Flushing, hypotension
Lab Findings	Positive DAT, hemolyzed intra- or post-transfusion specimen
Treatment	Avoid bedside leukocyte filtration
f. Embolism (air and particulate)	Result of air infusion via line; incidence is rare
Symptoms	Sudden shortness of breath; acute cyanosis; pain; cough; hypotension; cardiac arrhythmia
Lab Findings	N/A
Treatment	Position patient on left side with legs elevated above head and chest
g. Nonimmune hemolysis	Result of physical or chemical destruction of RBCs (e.g., heating, freezing, hemolytic drug, solution added to blood); incidence is rare
Symptoms	Hemoglobinuria
Lab Findings	Positive plasma free hemoglobin, positive DAT, obvious hemolysis in unit containing the blood
Treatment	Identify and eliminate cause
III. Delayed Immune-Mediated Transfusion Reactions	
a. Hemolytic	Anamnestic immune response to RBC antigens; incidence 1:11,000 to 1:50,000
Symptoms	Fever, anemia, mild jaundice
Lab Findings	Positive antibody screen, urinary hemosiderin and DAT; increased LDH, bilirubin
Treatment	Identify antibody and transfuse compatible blood as needed
b. Alloimmunization to RBC, WBC, platelet, and protein antigens	Immune response to RBC, WBC, or platelet antigens; incidence 1:100
Symptoms	Delayed hemolytic reaction
Lab Findings	Positive antibody screen and DAT
Treatment	Avoid unnecessary transfusions; give leukocyte-reduced blood if transfusion is necessary
c. Graft versus host	Donor lymphocytes attack recipient's host tissue; incidence is rare
Symptoms	Erythroderma, maculopapular rash, anorexia, nausea, vomiting, diarrhea, hepatitis, pancytopenia, fever

(*Continued on the following page*)

III. Delayed Immune-Mediated Transfusion Reactions *(Continued)*	
Lab Findings	Abnormal skin biopsy, incompatible HLA typing
Treatment	Methotrexate, corticosteroids; transfuse with irradiated blood products
IV. Delayed Non-Immune-Mediated Transfusion Reactions	
a. Iron overload	Result of chronic transfusions (greater than 100)
Symptoms	
Lab Findings	Symptoms associated with diabetes, cirrhosis, cardiomyopathy
Treatment	Increased iron levels Desferioxamine

ACE = angiotensin-converting enzyme; BUN = blood urea nitrogen; DAT = (Coombs') direct antiglobulin test; DIC = disseminated intravascular coagulation; ECG = electrocardiogram; HLA = human leukocyte antigen; Ig = immunoglobulin; LDH = lactate dehydrogenase; N/A = non applicable; PT = prothrombin time; PTT = partial thromboplastin time; RBC = red blood cell; WBC = white blood cell.

APPENDIX E

Introduction to CLIA 1988 & 1992

The acronym *CLIA* stands for Clinical Laboratory Improvement Amendments. In 1988, Congress passed CLIA in order to establish quality standards that would apply to laboratory testing nationwide. The standards ensure that, regardless of location, all clinical testing on human specimens is performed with accuracy, reliability, and timeliness. In 1992, CLIA final regulations distinguished between levels of test complexity. Three categories were established: waived complexity, moderate complexity (includes the subcategory of Provider-Performed Microscopy [PPM]), and high complexity testing. Permission to perform clinical laboratory testing in any or all categories requires the laboratory director to submit an application to enroll in the CLIA program, pay the applicable fee biennially, and meet quality requirements that correspond to the type of certificate that is obtained.

A Certificate of Waiver (COW) obtained by the appropriate health care practitioner allows qualified nursing or other health care personnel to perform procedures classified as waived testing in a health care practitioner's office or in a hospital nursing unit. Waived testing includes tests that are cleared by the Food and Drug Administration (FDA) for home use, have manufacturers' instructions to follow, and pose no harm to the patient if testing is performed incorrectly. The testing process utilizes controls. Examples of waived testing include dipstick urinalysis, fecal occult blood, ovulation testing, urine pregnancy tests, erythrocyte sedimentation rate (nonautomated), hemoglobin (copper sulfate method), and blood glucose (on glucose meters cleared by the FDA).

PPM laboratories perform moderately complex testing. This type of testing can be performed in a health care practitioner's office. A PPM certificate obtained by the health care practitioner allows the practitioner to perform moderately complex testing on specimens obtained during the patient's office visit, in addition to waived testing. A microscope is utilized to view the specimens during the patient's office visit. These moderately complex tests are performed on specimens in situations in which the accuracy of the findings would be compromised if a delay in testing were to occur. The testing process has no available controls. Examples of PPM testing include urine sediment examinations, potassium hydroxide preparations, pinworm examinations, fern tests, nasal smears for granulocytes, fecal leukocyte examinations, qualitative semen analysis, and wet mount testing for the presence or absence of bacteria, fungi, parasites, and cellular elements.

Hospital and reference laboratories perform tests of high complexity. The laboratory director must obtain the corresponding CLIA certificate and have personnel qualified to perform tests of high complexity.

APPENDIX F

Effects of Natural Products on Laboratory Values

The use of natural products has increased significantly, but to date, their preparation is unregulated. Their actions can affect normal and abnormal physiologic processes as well as interact with prescription medications. Their presence in the body, alone or in combination with over-the-counter products or prescription medications, may physiologically affect the intended target or cause analytical interference in such a way that the test result is affected. For this reason, it is important to note their use. The natural products listed here are contraindicated or are recommended for use with caution in patients with body system disorders or patients taking medications for these disorders. The requesting health care practitioner and laboratory should be advised if the patient is regularly using these products so that their potential effects can be taken into consideration when reviewing results.

This list is not all-inclusive. Questions regarding the potential benefits and contraindications of natural products should be referred to the appropriate health care practitioner. As a general recommendation, natural products and nutraceuticals are contraindicated during pregnancy and lactation.

Natural Products That May Affect Cardiovascular Disorders or Interact with Therapeutics (Including Hypertension and Hypotension)

Adonis
Aloe
Bromelain
Buckthorn
Cascara
Chinese rhubarb
Coleus
Dong quai
Elder
Ephedra
Ergot
Frangula
Garlic
Ginseng
Goldenseal
Green tea (with caffeine)
Henbane
Horsetail
Lily of the valley
Ma-huang
Reishi
Senna
Squill
Tylophora
Valerian
Yohimbe bark

Natural Products and Nutraceuticals That May Affect Endocrine Disorders or Interact with Therapeutics

Natural Products

Bilberry
Bitter melon
Bladderwrack
Blupleurum
Bugleweed
Echinacea
Ephedra
Fenugreek
Garcinia
Garlic
Ginseng
Goat's rue
Green tea (with caffeine)
Guggul
Licorice
Marshmallow
Olive leaf
Psyllium
Tylophora

Minerals

Chromium
Nutraceuticals
Dehydroepiandrosterone
α-Lipoic acid
Para-aminobenzoic acid
Thyroid extract

Natural Products and Nutraceuticals That May Affect Gastrointestinal Disorders or Interact with Therapeutics

Natural Products

Bromelain
Cascara
Chinese rhubarb
Dandelion
Psyllium
Senna

Nutraceuticals

Betaine hydrochloride

Natural Products and Nutraceuticals That May Affect Genitourinary Disorders or Interact with Therapeutics

Natural Products

Aloe
Arabinoxylane
Bladderwrack
Buckthorn
Cascara
Chinese rhubarb
Dandelion
Echinacea
Ephedra
Ergot
Frangula
Ginseng
Guarana
Horse chestnut
Horsetail
Licorice
Parsley oil (high doses)
Saw palmetto
Senna
Stinging nettle
White oak
White willow

Nutraceuticals

Creatine
Modified citrus pectin

Natural Products and Nutraceuticals That May Affect Bleeding Disorders or Interact with Therapeutics

Natural Products

Arnica
Astragalus
Bilberry
Bromelian

Cat's claw
Cayenne
Coleus
Cordyceps
Devil's claw
Dong quai
Evening primrose
Feverfew
Garlic
Ginger
Gingko
Ginseng
Grape seed
Green tea (with caffeine)
Guggui
Horse chestnut
Papaya
Red clover
Red yeast rice
Reishi
Turmeric
White willow

Nutraceuticals

Docosahexaenoic acid (DHA)
Fish oils (EPA and DHA)

Natural Products and Nutraceuticals That May Affect Hepatobiliary Disorders or Interact with Therapeutics

Natural Products

Alkanet
Alpine ragwort
Coltsfoot
Comfrey
Dusty miller
Forget-me-not
Germander
Groundsel
Olive leaf
Parsley oil (large doses)
Pennyroyal
Peppermint
Ragwort
Red yeast rice
Sweet clover
White oak
White willow

Nutraceuticals

Creatine

Natural Products and Amino Acids That May Affect Immune Disorders or Interact with Therapeutics

Natural Products

Astragalus
Black cohosh
Echinacea
Saw palmetto

Amino Acids

Arginine

Natural Products That May Affect Respiratory Disorders or Interact with Therapeutics

Artichoke
Cayenne
Chamomile
Cordyceps
Echinacea
Feverfew
Garlic
Peppermint oil
White willow

APPENDIX G

Standard Precautions (CDC Isolation Precautions)

Background and Summary

In January 1996, the Centers for Disease Control and Prevention (CDC) issued new guidelines for isolation precautions in hospitals. The guidelines, based on the latest epidemiologic information on transmission of infection in hospitals, are intended primarily for use in acute-care hospitals, although some of the recommendations may be applicable to subacute-care or extended-care facilities. The recommendations are not intended for use in day care, well care, or domiciliary care programs.

The revised guidelines contain two tiers of precautions. In the first, and most important, tier are precautions designed for the care of all patients in hospitals regardless of their diagnosis or presumed infection status. Implementation of these Standard Precautions is the primary strategy for successful nosocomial infection control. In the second tier are precautions designed only for the care of specified patients. These additional Transmission-Based Precautions are used for patients who are known or suspected to be infected or colonized with epidemiologically important pathogens that can be transmitted by airborne or droplet transmission or by contact with dry skin or contaminated surfaces.

Standard Precautions synthesize the major features of Universal (Blood and Body Fluid) Precautions (designed to reduce the risk of transmission of blood-borne pathogens) and Body Substance Isolation (designed to reduce the risk of transmission of pathogens from moist body substances). Standard Precautions apply to (1) blood; (2) all body fluids, secretions, and excretions *except sweat,* regardless of whether they contain visible blood; (3) nonintact skin; and (4) mucous membranes. Standard Precautions are designed to reduce the risk of transmission of recognized and unrecognized sources of infection in hospitals.

Transmission-Based Precautions are designed for patients documented or suspected to be infected or colonized with highly transmissible or epidemiologically important pathogens for which additional precautions beyond Standard Precautions are needed to interrupt transmission in hospitals. There are three types of Transmission-Based Precautions: Airborne Precautions, Droplet Precautions, and Contact Precautions. They may be combined for diseases that have multiple routes of transmission. When used either singly or in combination, they are to be used in addition to Standard Precautions.

Airborne Precautions are designed to reduce the risk of airborne transmission of infectious agents. Airborne transmission occurs by dissemination of either airborne droplet nuclei (small-particle residue [5 μm or smaller in size] of evaporated droplets that may remain suspended in the air for long periods) or dust particles containing the infectious agent. Microorganisms carried in this manner can be dispersed widely by air currents and may become inhaled by or deposited on a susceptible host within the same room or over a longer distance from the source patient, depending on environmental factors; special air handling and ventilation are required to prevent airborne transmission. Examples of diseases spread by airborne droplet nuclei include measles, varicella (including disseminated zoster), and tuberculosis.

Droplet Precautions are designed to reduce the risk of droplet transmission of infectious agents. Droplet transmission involves contact of the conjunctivae or the mucous membranes of the nose or mouth of a susceptible person with large-particle droplets (larger than 5 μm in size) containing microorganisms generated from a person who has a clinical disease or who is a carrier of the microorganism. Droplets are generated from the source person primarily during coughing, sneezing, or talking and during the performance of certain procedures such as suctioning and bronchoscopy. Transmission via large-particle droplets requires close contact between source and recipient persons because droplets do not remain suspended in the air and generally travel only short distances, usually 3 ft or less, through the air. Because droplets do not remain suspended in the air, special air handling and ventilation are not required to prevent droplet transmission. Examples of illnesses spread by large-particle droplets include invasive *Haemophilus influenzae* type B disease (including meningitis, pneumonia, epiglottitis, and sepsis); invasive *Neisseria meningitidis* disease (including meningitis, pneumonia, and sepsis); diphtheria (pharyngeal); mycoplasmal pneumonia; pertussis; pneumonic plague; streptococcal pharyngitis, pneumonia, or scarlet fever in infants and young children; adenovirus influenza; mumps; parvovirus B19; and rubella.

Contact Precautions are designed to reduce the risk of transmission of epidemiologically important microorganisms by direct or indirect contact. Direct-contact transmission involves skin-to-skin contact and physical transfer of microorganisms to a susceptible host from an infected or colonized person, such as occurs when personnel turn patients, bathe patients, or perform other patient care activities that require physical contact. Direct-contact transmission also can occur between two patients (e.g., by hand contact), with one serving as the source of infectious microorganisms and the other as a susceptible host. Indirect-contact transmission involves contact of a susceptible host with a contaminated intermediate object, usually inanimate, in the patient's environment. Examples of illnesses spread by direct contact include gastrointestinal, respiratory, skin, or wound infections or colonization with multidrug-resistant bacteria judged by the infection control program (based on current state, regional, or national recommendations) to be of special clinical and epidemiologic significance; enteric infections with a low infectious dose or prolonged environmental survival, including *Clostridium difficile;* for diapered or incontinent patients, enterohemorrhagic *Escherichia coli* O157:H7, *Shigella,* hepatitis A, or rotavirus; respiratory syncytial virus, parainfluenza virus, or enteroviral infections in infants and young children; viral/hemorrhagic conjunctivitis; viral hemorrhagic infections (Ebola, Lassa, or

Marburg); and skin infections that are highly contagious or that may occur on dry skin, including:

- Diphtheria (cutaneous)
- Herpes simplex virus (neonatal or mucocutaneous)
- Impetigo
- Major (noncontained) abscesses, cellulitis, or decubiti
- Pediculosis
- Scabies
- Staphylococcal furunculosis in infants and young children
- Zoster (disseminated or in the immunocompromised host)

Standard Precautions

Use the following Standard Precautions, or the equivalent, for the care of all patients.

Handwashing

Wash hands after touching blood, body fluids, secretions, excretions, and contaminated items, whether or not gloves are worn. Wash hands immediately after gloves are removed, between patient contacts, and when otherwise indicated to avoid transfer of microorganisms to other patients or environments. It may be necessary to wash hands between tasks and procedures on the same patient to prevent cross-contamination of different body sites.

Use a plain (nonantimicrobial) soap for routine handwashing.

Use an antimicrobial agent or a waterless antiseptic agent for specific circumstances (e.g., control of outbreaks or hyperendemic infections), as defined by the infection control program. (See Contact Precautions for additional recommendations on using antimicrobial and antiseptic agents.)

Gloves

Wear gloves (clean, nonsterile gloves are adequate) when touching blood, body fluids, secretions, excretions, and contaminated items.

Put on clean gloves just before touching mucous membranes and nonintact skin.

Change gloves between tasks and procedures on the same patient after contact with material that may contain a high concentration of microorganisms.

Remove gloves promptly after use, before touching noncontaminated items and environmental surfaces, and before going to another patient. Wash hands immediately to avoid transfer of microorganisms to other patients or environments.

Mask, Eye Protection, Face Shield

Wear a mask and eye protection or a face shield to protect mucous membranes of the eyes, nose, and mouth during procedures and patient care activities that are likely to generate splashes or sprays of blood, body fluids, secretions, and excretions.

Gown

Wear a gown (a clean, nonsterile gown is adequate) to protect skin and to prevent soiling of clothing during procedures and patient care activities that are likely to generate splashes or sprays of blood, body fluids, secretions, or excretions.

Select a gown that is appropriate for the activity and amount of fluid likely to be encountered.

Remove a soiled gown as promptly as possible. Wash hands to avoid transfer of microorganisms to other patients or environments.

Patient Care Equipment

Handle used patient care equipment soiled with blood, body fluids, secretions, and excretions in a manner that prevents skin and mucous membrane exposures, contamination of clothing, and transfer of microorganisms to other patients and environments.

Ensure that reusable equipment is not used for the care of another patient until it has been cleaned and reprocessed appropriately. Ensure that single-use items are discarded properly.

Environmental Control

Ensure that the hospital has adequate procedures for the routine care, cleaning, and disinfection of environmental surfaces, beds, bedrails, bedside equipment, and other frequently touched surfaces, and ensure that these procedures are being followed.

Linen

Handle, transport, and process used linen soiled with blood, body fluids, secretions, and excretions in a manner that prevents skin and mucous membrane exposures and contamination of clothing and that avoids transfer of microorganisms to other patients and environments.

Occupational Health and Blood-Borne Pathogens

Take care to prevent injuries when using needles, scalpels, and other sharp instruments or devices; when handling sharp instruments after procedures; when cleaning used instruments; and when disposing of used needles.

Never recap used needles or otherwise manipulate them using both hands, or use any other technique that involves directing the point of a needle toward any part of the body; rather, use either a one-handed "scoop" technique or a mechanical device designed for holding the needle sheath.

Do not remove used needles from disposable syringes by hand, and do not bend, break, or otherwise manipulate a used needle by hand.

Place used disposable syringes and needles, scalpel blades, and other sharp items in appropriate puncture-resistant containers, which are located as close as practical to the area in which the items were used, and place reusable syringes and needles in a puncture-resistant container for transport to the reprocessing area.

Use mouthpieces, resuscitation bags, or other ventilation devices as an alternative to mouth-to-mouth resuscitation methods in areas where the need for resuscitation is predictable.

Patient Placement

Place a patient who contaminates the environment or who does not (or cannot be expected to) assist in maintaining appropriate hygiene or environmental control in a private room. If a private room is not available, consult with infection control professionals regarding patient placement or other alternatives.

Transmission-Based Precautions

Airborne Precautions

In addition to Standard Precautions, use Airborne Precautions, or the equivalent, for patients known or suspected to be infected with microorganisms transmitted by airborne droplet nuclei (small-particle residue [5 μm or smaller in size] of evaporated droplets containing microorganisms that remain suspended in the air and that can be dispersed widely by air currents within a room or over a long distance).

Patient Placement

Place the patient in a private room that has (1) monitored negative air pressure in relation to the surrounding areas, (2) 6 to 12 air changes per hour, and (3) appropriate discharge of air outdoors or monitored high-efficiency filtration of room air before the air is circulated to other areas in the hospital.

Keep the room door closed and the patient in the room.

When a private room is not available, place the patient in a room with a patient who has active infection with the same microorganism but with no other infection (cohorting), unless otherwise recommended. When a private room is not available and cohorting is not desirable, consultation with infection control professionals is advised before patient placement.

Respiratory Protection

Wear respiratory protection when entering the room of a patient with known or suspected infectious pulmonary tuberculosis.

Susceptible persons should not enter the room of patients known or suspected to have measles (rubeola) or varicella (chickenpox) if other immune caregivers are available. If susceptible persons must enter the room of a patient known or suspected to have measles or varicella, they should wear respiratory protection. Persons immune to measles or varicella need not wear respiratory protection.

Patient Transport

Limit the movement and transport of the patient from the room to essential purposes only. If transport or movement is necessary, minimize patient dispersal of droplet nuclei by placing a surgical mask on the patient, if possible.

Additional Precautions for Preventing Transmission of Tuberculosis

Consult the CDC's "Guidelines for Preventing the Transmission of Tuberculosis in Health-Care Facilities" for additional prevention strategies.[1]

Droplet Precautions

In addition to Standard Precautions, use Droplet Precautions, or the equivalent, for a patient known or suspected to be infected with microorganisms transmitted by droplets (large-particle droplets [larger than 5 μm in size] that can be generated during coughing, sneezing, talking, or the performance of procedures).

Patient Placement

Place the patient in a private room. When a private room is not available, place the patient in a room with a patient who has active infection with the same microorganism but with no other infection (cohorting). When a private room is not available and cohorting is not achievable, maintain spatial separation of at least 3 ft between the infected patient and other patients and visitors.

Special air handling and ventilation are not necessary, and the door may remain open.

Mask

In addition to Standard Precautions, wear a mask when working within 3 ft of the patient. (Logistically, some hospitals may want to implement the wearing of a mask to enter the room.)

Patient Transport

Limit the movement and transport of the patient from the room to essential purposes only.

If transport or movement is necessary, minimize patient dispersal of droplets by masking the patient, if possible.

Contact Precautions

In addition to Standard Precautions, use Contact Precautions, or the equivalent, for specified patients known or suspected to be infected or colonized with epidemiologically important microorganisms that can be transmitted by direct contact with the patient (hand or skin-to-skin contact that occurs when performing patient care activities that require touching the patient's dry skin) or indirect contact (touching) with environmental surfaces or patient care items in the patient's environment.

Patient Placement

Place the patient in a private room. When a private room is not available, place the patient in a room with a patient who has active infection with the same microorganism but with no other infection (cohorting).

---

[1]Employees who received training in the year preceding the effective date of the standard need only receive training pertaining to any provisions not already included.

When a private room is not available and cohorting is not achievable, consider the epidemiology of the microorganism and the patient population when determining patient placement. Consultation with infection control professionals is advised before patient placement.

Gloves and Handwashing

In addition to wearing gloves as outlined under Standard Precautions, wear gloves (clean, nonsterile gloves are adequate) when entering the room.

During the course of providing care for a patient, change gloves after having contact with infective material that may contain high concentrations of microorganisms (fecal material and wound drainage).

Remove gloves before leaving the patient's environment and wash hands immediately with an antimicrobial agent or a waterless antiseptic agent. After glove removal and handwashing, ensure that hands do not touch potentially contaminated environmental surfaces or items in the patient's room to avoid transfer of microorganisms to other patients or environments.

Gown

In addition to wearing a gown as outlined under Standard Precautions, wear a gown (a clean, nonsterile gown is adequate) when entering the room if you anticipate that your clothing will have substantial contact with the patient, environmental surfaces, or items in the patient's room or if the patient is incontinent or has diarrhea, an ileostomy, a colostomy, or wound drainage not contained by a dressing.

Remove the gown before leaving the patient's environment. After gown removal, ensure that clothing does not contact potentially contaminated environmental surfaces to avoid transfer of microorganisms to other patients or environments.

Patient Transport

Limit the movement and transport of the patient from the room to essential purposes only.

If the patient is transported out of the room, ensure that precautions are maintained to minimize the risk of transmission of microorganisms to other patients and contamination of environmental surfaces or equipment.

Patient Care Equipment

When possible, dedicate the use of noncritical patient care equipment to a single patient (or cohort of patients infected or colonized with the pathogen requiring precautions) to avoid sharing between patients.

If use of common equipment or items is unavoidable, adequately clean and disinfect them before use for another patient.

Additional Precautions for Preventing the Spread of Vancomycin Resistance

Consult the Hospital Infection Control Practices Advisory Committee report on preventing the spread of vancomycin resistance for additional prevention strategies.

OSHA Blood-Borne Pathogens Standard

Who is Covered?

The Occupational Safety and Health Administration (OSHA) standard protects employees who may be occupationally exposed to blood and other potentially infectious materials, which includes but is not limited to physicians, physician assistants, nurses, nurse practitioners, and other health care employees in clinics and physicians' offices; employees of clinical and diagnostic laboratories; housekeepers in health care and other facilities; personnel in hospital laundries or commercial laundries that service health care or public safety institutions; tissue bank personnel; employees in blood banks and plasma centers who collect, transport, and test blood; free-standing clinic employees (e.g., hemodialysis clinics, urgent care clinics, health maintenance organization [HMO] clinics, and family planning clinics); employees in clinics in industrial, educational, and correctional facilities (e.g., employees who collect blood and clean and dress wounds); employees designated to provide emergency first aid; dentists, dental hygienists, dental assistants, and dental laboratory technicians; staff of institutions for the developmentally disabled; hospice employees; home health care workers; staff of nursing homes and long-term care facilities; employees of funeral homes and mortuaries; human immunodeficiency virus (HIV) and hepatitis B virus (HBV) research laboratory and production facility workers; employees handling regulated waste; custodial workers required to clean up contaminated sharps or spills of blood or other potentially infectious material (OPIM); medical equipment service and repair personnel; emergency medical technicians, paramedics, and other emergency medical service providers; firefighters, law enforcement personnel, and correctional officers (employees in the private sector, the federal government, or a state or local government in a state that has an OSHA-approved state plan); maintenance workers, such as plumbers, in health care facilities; and employees of substance abuse clinics.

Blood means human blood, blood products, or blood components (plasma, platelets, and serosanguineous fluids [e.g., exudates from wounds]). Also included are medications derived from blood, such as immune globulins, albumin, and factors VIII and IX. Other potentially infectious materials include human body fluids, such as saliva in dental procedures; semen; vaginal secretions; cerebrospinal, synovial, pleural, pericardial, peritoneal, and amniotic fluids; body fluids visibly contaminated with blood; unfixed human tissues or organs; HIV-containing cell or tissue cultures; and HIV-containing or HBV-containing culture media or other solutions.

Occupational exposure means a "reasonably anticipated skin, eye, mucous membrane, or parenteral contact [human bites that break the skin, which are most likely to occur in violent situations such as may be encountered by prison personnel and police and in emergency departments or psychiatric wards] with blood or other potentially infectious materials that may result from the performance of the employee's duties." The term *reasonably anticipated contact* includes the potential for contact and actual contact with blood or OPIM. Lack of history of blood exposures among designated first aid personnel of a particular manufacturing site, for instance, does not preclude coverage. Reasonably anticipated contact includes, among others, contact with blood or OPIM, including regulated waste, as well as incidents of needle sticks. A compliance

officer may document incidents in which an employee observes uncapped needles or contacts other regulated waste to substantiate occupational exposure.

Federal OSHA authority extends to all private sector employers with one or more employees, as well as federal civilian employees. In addition, many states administer their own occupational safety and health programs through plans approved under section 18(b) of the Occupational Safety and Health Act. These plans must adopt standards and enforce requirements that are at least as effective as federal requirements. Of the current 25 states and territories with plans, 23 cover the private and public (state and local governments) sectors and 2 cover the public sector only.

Determining occupational exposure and instituting control methods and work practices appropriate for specific job assignments are key requirements of the standard. The required written exposure control plan and methods of compliance show how employee exposure can be minimized or eliminated.

Exposure Control Plan

A written exposure control plan is necessary for the safety and health of workers. At a minimum, the plan must include the following:

Identify job classifications in which there is exposure to blood or other potentially infectious materials.

Explain the protective measures currently in effect in the acute-care facility or a schedule and methods of compliance to be implemented, including hepatitis B vaccination and postexposure follow-up procedures, how hazards are communicated to employees, personal protective equipment (PPE), housekeeping, and record keeping.

Establish procedures for evaluating the circumstances of an exposure incident.

The schedule of how and when the provisions of the standard will be implemented may be a simple calendar with brief notations describing the compliance methods, an annotated copy of the standard, or a part of another document, such as the infection control plan. The written exposure control plan must be available to workers and OSHA representatives and updated at least annually or whenever changes in procedures create new occupational exposures.

Who has Occupational Exposure?

The exposure determination must be based on the definition of occupational exposure without regard to personal protective clothing and equipment. Exposure determination begins by reviewing job classifications of employees within the work environment, and then making a list divided into two groups: classifications in which all of the employees have occupational exposure and classifications in which some of the employees have occupational exposure.

Where all employees are occupationally exposed, it is not necessary to list specific work tasks. Some examples include phlebotomists, laboratory technicians, physicians, nurses, nurse's aides, surgical technicians, and emergency department personnel.

Where only some of the employees have exposure, specific tasks and procedures causing exposure must be listed. Examples include ward clerks or secretaries, who occa-

sionally handle blood or infectious specimens, and housekeeping staff, who may be exposed to contaminated objects or environments some of the time.

When employees with occupational exposure have been identified, the next step is to communicate the hazards of the exposure to the employees.

Communicating Hazards to Employees

The initial training for current employees must be scheduled within 90 days of the effective date of the blood-borne pathogens standard, at no cost to the employee, and during working hours.[1] Training also is required for new workers at the time of their initial assignment to tasks with occupational exposure or when job tasks change, causing occupational exposure, and annually thereafter.

Training sessions must be comprehensive in nature, including information on blood-borne pathogens as well as on OSHA regulations and the employer's exposure control plan. Although HBV and HIV are specifically identified in the standard, the term *blood-borne pathogen* includes any pathogenic microorganism that is present in human blood or other potentially infectious materials and can infect and cause disease in persons who are exposed to blood containing the pathogen. Pathogenic microorganisms also can cause diseases such as hepatitis C, malaria, syphilis, babesiosis, brucellosis, leptospirosis, arboviral infections, relapsing fever, Creutzfeldt-Jakob disease, adult T-cell leukemia/lymphoma (caused by human T-cell leukemia/lymphoma virus [HTLV-I]), HTLV-I–associated myelopathy, diseases associated with HTLV-II, and viral hemorrhagic fever. The person conducting the training must be knowledgeable in the subject matter as it relates to acute care facilities.

Specifically, the training program must do the following:

- Explain the regulatory text and make a copy of the regulatory text accessible.
- Explain the epidemiology and symptoms of blood-borne diseases.
- Explain the modes of transmission of blood-borne pathogens.
- Explain the employer's written exposure control plan.
- Describe the methods to control transmission of HBV and HIV.
- Explain how to recognize occupational exposure.
- Inform workers about the availability of free hepatitis B vaccinations and vaccine efficacy, safety, benefits, and administration.
- Explain the emergency procedures for and reporting of exposure incidents.
- Inform workers of the postexposure evaluation and follow-up available from health care professionals.
- Describe how to select, use, remove, handle, decontaminate, and dispose of personal protective clothing and equipment.
- Explain the use and limitations of safe work practices, engineering controls (controls that isolate or remove the blood-borne pathogens hazard from the workplace; examples include needleless devices, shielded needle devices, blunt needles, plastic capillary tubes), and PPE.
- Explain the use of labels, signs, and color coding required by the standard.
- Provide a question-and-answer session on training.

In addition to communicating hazards to employees and providing training to identify and control hazards, other preventive measures must be taken to ensure employee protection.

Preventive Measures

Preventive measures such as hepatitis B vaccination, universal precautions, engineering controls, safe work practices, PPE, and housekeeping measures help reduce the risks of occupational exposure.

Hepatitis B Vaccination

The hepatitis B vaccination series must be made available within 10 working days of initial assignment to every employee who has occupational exposure. The hepatitis B vaccination must be made available without cost to the employee, at a reasonable time and place for the employee, by a licensed health care professional,[2] and according to recommendations of the U.S. Public Health Service, including routine booster doses.[3]

The health care professional designated by the employer to implement this part of the standard must be provided with a copy of the blood-borne pathogens standard. The health care professional must provide the employer with a written opinion stating whether the hepatitis B vaccination is indicated for the employee and whether the employee has received the vaccination.

Employers are not required to offer hepatitis B vaccination (1) to employees who have previously completed the hepatitis B vaccination series, (2) when immunity is confirmed through antibody testing, or (3) if vaccine is contraindicated for medical reasons. Participation in a prescreening program is not a prerequisite for receiving hepatitis B vaccination. Employees who decline the vaccination may request and obtain it at a later date, if they continue to be exposed. Employees who decline to accept the hepatitis B vaccination must sign a declination form, indicating that they were offered the vaccination but refused it. For more information, refer to "Immunization of Health-Care Workers: Recommendations of ACIP and HICPAC" (*MMWR Morbidity and Mortality Weekly Report,* vol 46, no. RR-18, 1997).

Universal Precautions

The most important measure to control transmission of HBV and HIV is to treat all human blood and other potentially infectious materials *as if they were* infectious for HBV and HIV. (Coverage under this definition also extends to blood and tissues of experimental animals who are infected with HIV or HBV.) Application of this approach is referred to as *universal precautions. Blood and certain body fluids from all acute-care patients should be considered as potentially infectious materials.*[4] These fluids cause *contamination,* defined in the standard as "the presence or the reasonably anticipated presence of blood or other potentially infectious materials on an item or surface."

---

[2]A licensed health care professional is a person whose legally permitted scope of practice allows him or her to perform independently the activities required under paragraph (f) of the standard regarding hepatitis B vaccination and postexposure and follow-up.

[3]Health care professionals can call the CDC disease information hotline (404-332-4555, extension 234), for updated information on hepatitis B vaccination.

[4]See also "Recommendations for Prevention of HIV Transmission in Health-Care Settings" (*MMWR Morbidity and Mortality Weekly Report,* vol 36(2S), August 21, 1987).

Alternative concepts in infection control are called *Body Substance Isolation* and *Standard Precautions.* These methods define all body fluids and substances as infectious. These methods incorporate not only the fluids and materials covered by this standard, but also expand coverage to include all body fluids and substances. These concepts are acceptable alternatives to Universal Precautions, provided that facilities using them adhere to all other provisions of this standard.

Methods of Control

Engineering and Work Practice Controls

Engineering and work practice controls are the primary methods used to control the transmission of HBV and HIV in acute-care facilities. Engineering controls isolate or remove the hazard from employees and are used in conjunction with work practices. Personal protective equipment also is used when occupational exposure to blood-borne pathogens remains even after instituting these controls. Engineering controls must be examined and maintained, or replaced, on a scheduled basis. Some engineering controls that apply to acute-care facilities and are required by the standard include the following:

- Use puncture-resistant, leak-proof containers, color-coded red or labeled, according to the standard (see table), to discard contaminated items such as needles, broken glass, scalpels, or other items that could cause a cut or puncture wound.
- Use puncture-resistant, leak-proof containers, color-coded red or labeled, to store contaminated reusable sharps until they are properly reprocessed.
- Store and process reusable contaminated sharps in a way that ensures safe handling. Use a mechanical device to retrieve used instruments from soaking pans in decontamination areas.
- Use puncture-resistant, leak-proof containers to collect, handle, process, store, transport, or ship blood specimens and potentially infectious materials. Label these specimens if shipped outside the facility. Labeling is not required when specimens are handled by employees trained to use Universal Precautions with all specimens and when these specimens are kept within the facility.

Labeling Requirements

Item	No Label Needed If Universal Precautions Are Used and Specific Use of Container Is Known to All Employees	Biohazard Label	Red Container
Regulated waste container (e.g., contaminated sharps container)		X	or X

Item	No Label Needed If Universal Precautions Are Used and Specific Use of Container Is Known to All Employees		Biohazard Label		Red Container	
Reusable contaminated sharps container (e.g., surgical instruments soaking in a tray)			X	or	X	
Refrigerator/freezer holding blood or other potentially infectious material					X	
Containers used for storage, transport, or shipping of blood			X	or	X	
Blood/blood-borne products for clinical use	X					
Individual specimen containers of blood or other potentially infectious materials remaining in facility	X	or	X	or	X	
Contaminated equipment needing service (e.g., dialysis equipment, suction apparatus)			X Plus a label specifying where the contamination exists			
Specimens and regulated waste shipped from the primary facility to another facility for service or disposal			X	or	X	
Contaminated laundry	*	or	X	or	X	
Contaminated laundry sent to another facility that does not use universal precautions			X	or	X	

*Alternative labeling or color coding is sufficient if it permits all employees to recognize containers as requiring compliance with universal precautions.

Similarly, work practice controls reduce the likelihood of exposure by altering the manner in which the task is performed. All procedures must minimize splashing, spraying, splattering, and generation of droplets. Work practice requirements include the following:

- Wash hands when gloves are removed and as soon as possible after contact with blood or other potentially infectious materials.
- Provide and make available a mechanism for immediate eye irrigation, in the event of an exposure incident.
- Do not bend, recap, or remove contaminated needles unless required to do so by specific medical procedures or the employer can show that no alternative is feasible. In these instances, use mechanical means, such as forceps or a one-handed technique, to recap or remove contaminated needles.
- Do not shear or break contaminated needles.
- Discard contaminated needles and sharp instruments in puncture-resistant, leakproof, red- or biohazard-labeled containers[5] that are accessible, maintained upright, and not allowed to be overfilled.
- Do not eat, drink, smoke, apply cosmetics, or handle contact lenses in areas of potential occupational exposure. (*Note:* Use of hand lotions is acceptable.)
- Do not store food or drink in refrigerators or on shelves where blood or potentially infectious materials are present.
- Use red labels, or affix biohazard labels to, containers to store, transport, or ship blood or other potentially infectious materials, such as laboratory specimens (Figure Appendix G–1).
- Do not use mouth pipetting to suction blood or other potentially infectious materials; it is prohibited.

Additional Information on Engineering Controls

Effective Engineering Controls ECRI: ECRI (formerly Emergency Care Research Institute), designated as an evidence-based practice center by the Agency for

FIGURE G–1

[5]Biohazard labeling requires a fluorescent orange or orange-red label with the biologic hazard symbol as well as the word *Biohazard* in contrasting color affixed to the bag or container.

Healthcare Research and Quality, is a nonprofit international health services research organization. Their web site includes a discussion of the June 1998 issue of ECRI's *Health Devices,* which evaluated 19 needle stick–prevention devices, and provides information on how to obtain this document (available at: www.healthcare.ecri.org/site/whatsnew/press.releases/980724hdneedle.html).

Food and Drug Administration (FDA) Safety Alert: Needlestick and other risks from hypodermic needles on secondary IV administration sets—piggyback and intermittent IV (available at: www.fda.gov/cdrh/safety.html). This document warns of the risk of needlestick injuries from the use of hypodermic needles as a connection between two pieces of intravenous (IV) equipment. It also describes characteristics of devices that have the potential to decrease the risk of needle stick injuries.

International Health Care Worker Safety Center, University of Virginia: Their web site contains a page that features a list of safety devices with manufacturers and specific product names (available at: www.people.virginia.edu/epinet/products.html).

National Institute for Occupational Safety and Health (NIOSH): Sharps disposal containers (available at: www.cdc.gov/niosh/sharps1.html). This document features information on selecting, evaluating, and using sharps disposal containers.

Occupational Safety and Health Administration (OSHA): Glass capillary tubes: Joint Safety Advisory about potential risks (available at: www.oshaslc.gov/OshDoc/Interpdata/I19990222.html). This document describes safer alternatives to conventional glass capillary tubes.

Occupational Safety and Health Administration (OSHA): Needlestick injuries (available at: www.osha-slc.gov/SLTC/needlestick/index.html). This web page features recent news, recognition, evaluation, controls, compliance, and links to information on effective engineering controls.

Safety Sharp Device Contract: The Veterans Administration web site contains a page that features safety sharp devices on contract with the U.S. Department of Veterans Affairs (VA) (available at: www.va.gov/vasafety/osh-issues/needlesafety/safetysharpcontracts.htm).

SHARPS Injury Control Program: This program was established by Senate Bill 2005 to study sharps injuries in hospitals, skilled nursing facilities, and home health agencies in California. Their web site features a beta version of Safety Enhanced Device Database Listing by Manufacturer (available at: www.ohb.org/sharps.htm).

Training for Development of Innovative Control Technologies (TDICT) Project: Their web site contains a page that features safety feature evaluation forms for specific devices (available at: www.tdict.org/criteria.html).

Personal Protective Equipment

In addition to instituting engineering and work practice controls, the standard requires that appropriate PPE be used to reduce worker risk of exposure. Personal protective equipment is specialized clothing or equipment used by employees to protect against direct exposure to blood or other potentially infectious materials. Protective equipment must not allow blood or other potentially infectious materials to pass through to workers' clothing, skin, or mucous membranes. This equipment includes, but is not limited to, gloves, gowns, laboratory coats, face shields or masks, eye protection, and

resuscitator devices. Hypoallergenic gloves, glove liners, powderless gloves, or other similar alternatives must be readily available and accessible at no cost to employees who are allergic to the gloves normally provided.

The employer is responsible for providing, maintaining, laundering, disposing of, replacing, and ensuring the proper use of PPE. The employer is responsible for ensuring that workers have access to the protective equipment, at no cost, including proper sizes and types that take allergic conditions into consideration.

An employee may temporarily and briefly decline to wear PPE under rare and extraordinary circumstances and when, in the employee's professional judgment, wearing PPE prevents the delivery of health care or public safety services or poses an increased or life-threatening hazard to employees. In general, appropriate PPE is expected to be used whenever occupational exposure may occur.

The employer also must ensure that employees observe the following precautions for safely handling and using PPE:

- Remove all PPE immediately after contamination and on leaving the work area, and place in an appropriately designated area or container for storing, washing, decontaminating, or discarding.
- Wear appropriate gloves when contact with blood, mucous membranes, nonintact skin (e.g., skin with dermatitis, hangnails, cuts, abrasions, chafing, acne), or potentially infectious materials is anticipated; when performing vascular access procedures[6]; and when handling or touching contaminated items or surfaces.
- Provide hypoallergenic gloves, liners, or powderless gloves or other alternatives to employees who need them.
- Replace disposable, single-use gloves as soon as possible when contaminated or if torn or punctured, or barrier function is compromised.
- Do not reuse disposable (single-use) gloves.
- Decontaminate reusable (utility) gloves after each use, and discard if they show signs of cracking, peeling, tearing, puncturing, deteriorating, or failing to provide a protective barrier.
- Use full face shields or face masks with eye protection, goggles, or eyeglasses with side shields when splashes of blood and other bodily fluids may occur and when contamination of the eyes, nose, or mouth can be anticipated (e.g., during invasive and surgical procedures).
- Also wear surgical caps or hoods and shoe covers or boots when gross contamination may occur, such as during surgery and autopsy procedures.

Remember: The selection of appropriate PPE depends on the quantity and type of exposure expected.

Housekeeping Procedures

Equipment

The employer must ensure a clean and sanitary workplace. Contaminated work surfaces must be decontaminated with a disinfectant on completion of procedures; when

[6]Phlebotomists in volunteer blood donation centers are exempt in certain circumstances. See section (d)(3)(ix)(D) of the standard for specific details.

contaminated by splashes, spills, or contact with blood or other potentially infectious materials; and at the end of the work shift. Surfaces and equipment protected with plastic wrap, foil, or other nonabsorbent materials must be inspected frequently for contamination; these protective coverings must be changed when found to be contaminated.

Waste cans and pails must be inspected and decontaminated on a regularly scheduled basis. Broken glass should be cleaned up with a brush or tongs; never pick up broken glass with hands, even when wearing gloves.

Waste

Waste removed from the facility is regulated by local and state laws. Special precautions are necessary when disposing of contaminated sharps and other contaminated waste and include the following:

- Dispose of contaminated sharps in closable, puncture-resistant, leak-proof, red- or biohazard-labeled containers (see table earlier).
- Place other regulated waste[7] in closable, leak-proof, red- or biohazard-labeled bags or containers. If outside contamination of the regulated waste container occurs, place it in a second container that is closable, leak-proof, and appropriately labeled.

Laundry

Laundering contaminated articles, including employee laboratory coats and uniforms meant to function as PPE, is the responsibility of the employer. Contaminated laundry is handled as little as possible with minimum agitation. This can be accomplished through the use of a washer and dryer in a designated area on-site, or the contaminated items can be sent to a commercial laundry. The following requirements should be met with respect to contaminated laundry:

- Bag contaminated laundry as soon as it is removed and store in a designated area or container.
- Use red laundry bags or those marked with the biohazard symbol unless universal precautions are in effect in the facility, and all employees recognize the bags as contaminated and have been trained in handling the bags.
- Clearly mark laundry sent off-site for cleaning, by placing it in red bags or bags clearly marked with the orange biohazard symbol; use leak-proof bags to prevent soak-through.
- Wear gloves or other protective equipment when handling contaminated laundry.

What to do if an Exposure Incident Occurs

An exposure incident is the specific eye, mouth, or other mucous membrane, nonintact skin, or parenteral contact with blood or other potentially infectious materials that

[7]Regulated waste includes liquid or semiliquid blood or other potentially infectious materials; items contaminated with these fluids and materials, which could release these substances in a liquid or semiliquid state, if compressed; items caked with dried blood or other potentially infectious materials that are capable of releasing these materials during handling; contaminated sharps; and pathologic and microbiologic wastes containing blood or other potentially infectious materials.

results from the performance of an employee's duties. An example of an exposure incident is a puncture from a contaminated sharp.

The employer is responsible for establishing the procedure for evaluating exposure incidents. When evaluating an exposure incident, immediate assessment and confidentiality are crucial issues. Employees should report exposure incidents immediately to enable timely medical evaluation and follow-up by a health care professional as well as a prompt request by the employer for testing of the source individual's blood for HIV and HBV. The "source individual" is any patient whose blood or body fluids are the source of an exposure incident to the employee.

At the time of the exposure incident, the exposed employee must be directed to a health care professional. The employer must provide the health care professional with a copy of the blood-borne pathogens standard; a description of the employee's job duties as they relate to the incident; a report of the specific exposure, including route of exposure; relevant employee medical records, including hepatitis B vaccination status; and results of the source individual's blood tests, if available. At that time, a baseline blood sample should be drawn from the employee, if he or she consents. If the employee elects to delay HIV testing of the sample, the health care professional must preserve the employee's blood sample for at least 90 days.[8]

Testing the source individual's blood does not need to be repeated if the source individual is known to be infectious for HIV or HBV; testing cannot be done in most states without written consent.[9] The results of the source individual's blood tests are confidential. As soon as possible, however, the test results of the source individual's blood must be made available to the exposed employee through consultation with the health care professional.

After postexposure evaluation, the health care professional provides a written opinion to the employer. This opinion is limited to a statement that the employee has been informed of the results of the evaluation and told of the need, if any, for any further evaluation or treatment. The employer must provide a copy of the written opinion to the employee within 15 days. This is the only information shared with the employer after an exposure incident; all other employee medical records are confidential.

All evaluations and follow-up must be available at no cost to the employee and at a reasonable time and place, performed by or under the supervision of a licensed physician or another licensed health care professional, such as a nurse practitioner, and according to recommendations of the U.S. Public Health Service guidelines current at the time of the evaluation and procedure. In addition, all laboratory tests must be conducted by an accredited laboratory and at no cost to the employee.

Record Keeping

There are two types of records required by the blood-borne pathogens standard: medical and training. A medical record must be established for each employee with occu-

---

[8]If, during this time, the employee elects to have the baseline sample tested, testing is performed as soon as feasible.

[9]If consent is not obtained, the employer must show that legally required consent could not be obtained. Where consent is not required by law, the source individual's blood, if available, should be tested and the results documented.

pational exposure. This record is confidential and is kept separate from other personnel records. This record may be kept on-site or may be retained by the health care professional who provides services to employees. The medical record contains the employee's name, social security number, hepatitis B vaccination status (including the dates of vaccination), and the written opinion of the health care professional regarding the hepatitis B vaccination. If an occupational exposure occurs, reports are added to the medical record to document the incident and the results of testing after the incident. The postevaluation written opinion of the health care professional is also part of the medical record. The medical record also must document what information has been provided to the health care provider. Medical records must be maintained 30 years past the last date of employment of the employee.

Emphasis is on confidentiality of medical records. No medical record or part of a medical record should be disclosed without direct, written consent of the employee or as required by law.

Training records document each training session and are to be kept for 3 years. Training records must include the date, content outline, trainer's name and qualifications, and names and job titles of all persons attending the training sessions.

If the employer ceases to do business, medical and training records are transferred to the successor employer. If there is no successor employer, the employer must notify the Director of the National Institute for Occupational Safety and Health, U.S. Department of Health and Human Services, for specific directions regarding disposition of the records at least 3 months before disposal.

On request, medical and training records must be made available to the Assistant Secretary of Labor of Occupational Safety and Health. Training records must be available to employees on request. Medical records can be obtained by the employee or anyone having the employee's written consent. Additional record keeping is required for employers with 11 or more employees (see OSHA's "Recordkeeping Guidelines for Occupational Injuries and Illnesses" for more information.)

Other Sources of OSHA Assistance

Consultation Programs

Consultation assistance is available to employers who want help in establishing and maintaining a safe and healthful workplace. Largely funded by OSHA, the service is provided at no cost to the employer. Primarily developed for smaller employers with more hazardous operations, the consultation service is delivered by state government agencies or universities employing professional safety consultants and health consultants. Comprehensive assistance includes an appraisal of all mechanical, physical work practice, and environmental hazards of the workplace and all aspects of the employer's present job safety and health program. No penalties are proposed or citations issued for hazards identified by the consultant.

Voluntary Protection Programs

Voluntary protection programs and on-site consultation services, when coupled with an effective enforcement program, expand worker protection to help meet the goals of the Occupational Safety and Health Act. The three voluntary protection programs—

Star, Merit, and Demonstration—are designed to recognize outstanding achievement by companies that have incorporated comprehensive safety and health programs successfully into their total management system. They motivate others to achieve excellent safety and health results in the same outstanding way, and they establish a cooperative relationship between employers, employees, and OSHA.

Employee Training

All employees who have occupational exposure to blood-borne pathogens should receive training on the epidemiology, symptoms, and transmission of blood-borne pathogen diseases. In addition, the training program covers, at a minimum, the following elements:

- A copy and explanation of the standard
- An explanation of the Engineering Control Plan and how to obtain a copy
- An explanation of methods to recognize tasks and other activities that may involve exposure to blood and other potentially infectious materials, including what constitutes an exposure incident
- An explanation of the use and limitations of engineering controls, work practices, and PPE
- An explanation of the types, uses, location, removal, handling, decontamination, and disposal of PPE
- An explanation of the basis for PPE selection
- Information on the hepatitis B vaccine, including information on its efficacy, safety, and method of administration; the benefits of being vaccinated; and that the vaccine will be offered free of charge
- Information on the appropriate actions to take and persons to contact in an emergency involving blood or OPIM
- An explanation of the procedure to follow if an exposure incident occurs, including the method of reporting the incident and the medical follow-up that will be made available
- Information on the postexposure evaluation and follow-up that the employer is required to provide for the employee after an exposure incident
- An explanation of the signs and labels or color coding required by the standard and used at this facility
- An opportunity for interactive questions and answers with the person conducting the training session

For more information on grants and training and education, contact the OSHA Training Institute, Office of Training and Education, 1555 Time Drive, Des Plaines, IL 60018 (708-297-4810). For more information on AIDS, contact the Centers for Disease Control National AIDS Clearinghouse (800-458-5231).

INDEX

A

A_1AT (α_1-antitrypsin), 164–167
A_1AT phenotype (α_1-antitrypsin phenotype), 164–167
A_{1c}. *See* Glycolated hemoglobin A_{1c}.
A/a gradient. *See* Alveolar/arterial gradient.
a/A ratio. *See* Arterial/alveolar oxygen ratio.
AAT, 164–167
AAT phenotype, 164–167
Abdomen
  angiogram/arteriogram of, 69–74
  CT of, 421–425, 469–473
  KUB study of, 833–836
  laparoscopy of, 848–851
  liver-spleen scan of, 872–877
  lymph node sonography of, 1275–1278
  Meckel's diverticulum scan of, 943–947
  MRI of, 907–911
  pelvic sonography of, 1282–1285
Abdominal abscess, CT of, 421, 422
Abdominal aortic disease, MRI of, 908
Abdominal enlargement, fibroids and, 1338
Abdominal injury
  amylase levels in, 63
  CT of, 421
  laparoscopic evaluation of, 848
  liver-spleen scan after, 873
  splenic ultrasonography after, 1299
Abdominal malignancy, peritoneal fluid analysis and, 1022
Abdominal mass
  fecal analysis and, 635
  KUB study of, 834
  laparoscopic evaluation of, 848
  liver-spleen scan of, 873
  MRI of, 908
Abdominal obstruction, CT of, 421, 422
Abdominal pain
  acetaminophen intoxication and, 66
  KUB study of, 834
  laparoscopic evaluation of, 848
  Meckel's diverticulum scan of, 943, 944
  proctosigmoidoscopy for, 1080
  urine porphyrins and, 1052
Abdominal vascular disease, MRA of, 904
Abdominal wall defects, fetal, AFP and, 647
Abetalipoprotein deficiency, fecal fat and, 638
Abetalipoproteinemia
  Apo A and, 168
  HDLC and, 376
  LDLC and, 376
  TG and, 1237
  vitamin A and, 1370
  vitamin E and, 1365
ABO blood groups, 272–276
  IgM and, 797
ABO hemolytic reactions, transfusion-related, 1423
Abortion
  AFP and, 647
  HCG and, 773
  progesterone and, 1084, 1085
ABR (auditory brainstem response), 627, 628–629
Abrasions, slit-lamp biomicroscopy of, 1183
Abruptio placentae
  FDP and, 650
  ultrasonography of, 1279
Abscess, 70, 94
  abdominal CT of, 421, 422
  angiographic CT of, 426
  biliary/liver CT of, 430
  bronchoscopy for, 288
  CA 125 in, 296
  cerebral CT of, 434, 435
  ECG of, 587
  gallium scan of, 669
  hepatic ultrasonography of, 1272
  liver-spleen scan of, 873
  lymph node ultrasonography and, 1276
  mammogram of, 940, 941

Abscess (*continued*)
MRI of, 908, 913, 917, 929, 933, 939
pancreatic CT of, 448
pelvic CT of, 452
pelvic ultrasonography of, 1286
pituitary CT of, 457
proctosigmoidoscopy and, 1080
prostate ultrasonography of, 1293
renal CT of, 461
renal ultrasonography of, 1269
renogram of, 1157
retrograde ureteropyelography of, 1164
scrotal ultrasonography of, 1296
splenic CT of, 470
splenic ultrasonography of, 1299
thoracic CT of, 475
WBC count and, 1377
WBC scan of, 1381
Abscess drainage, breast ultrasonography for, 1266
Absolute white blood cell count, 1374
Abuse. *See specific type, e.g.,* Drug abuse.
ACA (anticardiolipin antibody), 130–132
Acalculous cholecystitis, hepatobiliary scan for, 754
Acanthocytes, 1144, 1146–1147
CBC and, 417
Accessory spleen, ultrasonography of, 1299
AcCHS. *See* Pseudocholinesterase.
ACE (angiotensin-converting enzyme), 97–100
Acetaminophen, 65–69
lactic acid and, 843
Acetaminophen intoxication, 66
Acetoacetate, 828–833
Acetone, 828–833
N-Acetyl procainamide, 104–110
Acetylcholine receptor (AChR) antibody, 1–3
Acetylcholinesterase (AChE), 1108, 1132–1134
amniotic fluid analysis and, 59
Acetylsalicylic acid, 65–69
Achalasia
barium swallow and, 193
capsule endoscopy for, 319
esophageal manometry for, 613
UGI series and, 1310
AChE. *See* Acetylcholinesterase (AChE).
Achondroplasia, x-ray of, 1130
AChR (acetylcholine receptor) antibody, 1–3
Acid clearing, esophageal manometry and, 613
Acid elution slide test, 836–838
Acid hemolysis test, for paroxysmal nocturnal hemoglobinuria, 720–722
Acid perfusion (Bernstein test), 613–616
Acid phosphatase, prostatic, 3–6
Acid reflux
esophageal manometry and, 613
test for, 613–616
Acid-base balance
blood gases and, 264–265
carbon dioxide and, 322
chloride and, 355
potassium and, 1069, 1073
serum osmolality and, 981
sodium and, 1186
Acid-fast bacilli (AFB) culture, 509–515
Acidosis
calcium and, 305, 310
chloride and, 355
diabetic
catecholamines and, 331, 335
magnesium and, 897
ketones and, 830
lactic. *See* Lactic acidosis.
lactic acid and, 842
metabolic. *See* Metabolic acidosis.
potassium and, 1069
renal tubular. *See* Renal tubular acidosis.
respiratory. *See* Respiratory acidosis.
Aciduria, methylmalonic, ketones and, 830
Acoustic nerve impairment, 1193
Acoustic neuroma
ABR and, 628
MRI of, 913
Acquired angioedema, C4 complement and, 409
Acquired immune hemolytic anemia, osmotic fragility and, 984
Acquired immunodeficiency syndrome (AIDS). *See also* Human immunodeficiency virus (HIV).
Alzheimer's disease markers in, 40
β_2-M and, 961
CD4/CD8 profile in, 338, 339
gallium scan for, 669
human immunodeficiency virus in, 776
Mycobacterium culture and smear for, 510
platelet antibodies and, 1034
sputum cytology and, 555
tuberculin skin test and, 1247
viral culture for, 541
zinc and, 1384
Acquired methemoglobinemia, 954
Acquired porphyria, 1052
Acquired pyruvate kinase deficiency, 1120
Acrodermatitis enteropathica, zinc and, 1384
Acromegaly
calcium and, 305, 313
creatinine and, 500, 503
GH tests and, 718

glucagon and, 690
glucose and, 693
insulin response test and, 807
phosphorus and, 1026
TBG and, 1224
WBC count and, 1377
ACTH (adrenocorticotropic hormone), ectopic production of, 488
tumors associated with. *See* ACTH-producing tumors.
ACTH (adrenocorticotropic hormone) tests, 9–15
cortisol and, 486, 487
ACTH-producing tumors, ectopic
ACTH levels in, 13
DHEAS and, 569
Actinomyces, Pap smear and, 1001
Activated charcoal
anticonvulsant toxicity and, 142–143
antidepressant toxicity and, 151
antipsychotic toxicity and, 159
digoxin toxicity and, 107
haloperidol toxicity and, 159
lithium toxicity and, 159
methemoglobin toxicity and, 955
salicylate toxicity and, 67
Activated partial thromboplastin time (APTT), 1010–1013
lupus anticoagulant antibodies and, 885
PT tests and, 1104
Activity intolerance, Holter monitor and, 764
Acute intermittent porphyria
ADH levels in, 153
carbon dioxide and, 323
cholesterol and, 380
respiratory acidosis and, 265
TBG and, 1224
Acute leukemia(s), iron and, 824
Acute myelogenous leukemia
PAP levels in, 4
platelet antibodies and, 1034
Acute tubular necrosis
MRI and, 908
renogram and, 1157
Acute-phase inflammatory response, prealbumin and, 1078
Acute-phase reactions
C3 and C4 complement and, 409
total complement and, 411
Addison's disease
ACTH levels in, 13
aldosterone levels in, 25
calcium and, 305
chloride and, 355
cortisol and, 488
DHEAS and, 569
eosinophil count in, 603
fecal fat and, 638
glucose and, 694
GTT and, 700
magnesium and, 897
potassium and, 1069, 1074
renin and, 1153
serum sodium and, 1186
sweat chloride and, 359
WBC count and, 1377
Adenoma
adrenal. *See* Adrenal adenoma.
aldosterone levels in, 25
CT of, 457
glucose and, 694
hepatic ultrasonography of, 1272, 1273
liver-spleen scan of, 873
parathyroid scan for, 1007
thyroid scan and, 1214, 1302
Adenomyosis, MRI of, 933
Adenopathy
lymphangiogram and, 893
MRI and, 929
Adenosine diphosphate (ADP)
magnesium and, 897, 900
PK and, 1119
Adenosine triphosphate (ATP), PK and, 1120
Adenosis, vaginal, Pap smear and, 1001
Adenovirus, viral culture and, 541, 542
ADH. *See* Antidiuretic hormone (ADH).
ADHD (attention-deficit hyperactivity disorder), 150
Adhesions
hysterosalpingography and, 788
laparoscopy and, 849, 853
ADNase-B (antideoxyribonuclease-B), 146–147
Adnexal tumor, ultrasonography of, 1286
Adolescent(s), age-specific communication and, 1420
ADP. *See* Adenosine diphosphate (ADP).
Adrenal adenoma
ACTH levels in, 13
aldosterone-secreting, 1153
angiography of, 75
cortisol and, 488
CT of, 461
Adrenal carcinoma
ACTH levels in, 13
angiography of, 75
CT of, 461
glucose and, 694
Adrenal dysfunction, RBC count and, 1135
Adrenal failure, urine sodium and, 1189

Adrenal gland
ADH levels in, 153
angiogram/arteriogram of, 74–79
cortisol and, 488
LDH in, 839
scintiscan of, 6–9
Adrenal hyperfunction, urine sodium and, 1189
Adrenal hyperplasia
angiography of, 75
congenital. *See* Congenital adrenal hyperplasia (CAH).
CT of, 461
testosterone and, 1207
Adrenal insufficiency
ACTH levels in, 13
DHEAS and, 569
GTT and, 700
primary. *See* Addison's disease.
prolactin and, 1087
Adrenal tumor
CT of, 422
estradiol and, 621
virilizing, DHEAS and, 569
Adrenocortical hyperfunction
amino acid blood screen in, 44
GH tests and, 719
Adrenocortical insufficiency, magnesium and, 897
Adrenocortical tumors, testosterone and, 1207
Adrenocorticoid insufficiency, osmolality and, 981
Adrenocorticotropic hormone. *See* ACTH *entries.*
Adult(s), age-specific communication and, 1420–1421
Adult lymphoblastic (T-cell) leukemia, HTLV-I and, 780
AEPs (auditory evoked potentials), 630
Aerosol lung scan, 881–885
Afibrinogenemia
APTT and, 1011
PT and, 1105
AFP. *See* α_1-Fetoprotein (AFP).
A/G ratio (albumin/globulin ratio), 19–21
Agammaglobulinemia, IgE and, 795
Agap (anion gap), 100–103
Age (aging)
ACE units and, 97
ACTH units and, 10
A/G ratios and, 19
aldolase units and, 22
aldosterone units and, 24
ammonia units and, 54
DHEAS and, 569
tearing deficiency and, 1175
VDRL testing and, 1204
Age-specific communication guidelines, 1418–1421
Agglutination
cold, in MCHC, 735
cold agglutinin titer and, 393–395
Agitation, antidepressant toxicity and, 151
Agranulocytosis
bone marrow biopsy and, 208
procainamide toxicity and, 107
AIDS. *See* Acquired immunodeficiency syndrome (AIDS).
Airborne precautions, 1435–1436
Air-contrast barium enema, 189–192
Airway anomalies, PFTs and, 1113
Airway obstruction
bronchoscopy and, 288
carbon dioxide and, 323
Airway patency, 288
Airway resistance, plethysmography and, 1043
Akinesia, blood pool imaging and, 278
δ-ALA, 52–54
Alanine, 42, 47f
Alanine aminotransferase (ALT), 15–18
acetaminophen intoxication and, 66
Albright-type renal disease, potassium and, 1074
Albumen, zinc and, 1385
Albumin, 18–21. *See also* Microalbumin.
calcium and, 305

BAERs (brainstem auditory evoked responses), 627–630
Baker's cyst, arthroscopy of, 176
Bandemia, definition of, 375
Banked blood transfusion, potassium and, 1070
BAO (basal acid output), 672, 673
Barbiturate(s), stress testing and, 632
Barbiturate abuse, 570–571, 572
Bard BTA (bladder cancer urine markers), 255–257
Barium enema (BE), 189–192
  abnormal, CT colonoscopy after, 434
Barium swallow, 192–195
Bartter's syndrome
  aldosterone levels in, 25
  magnesium and, 901
  renin and, 1153
Basal acid output (BAO), 672, 673
Basal cell carcinoma, biopsy of, 249
Basophil(s), 1374, 1375–1376
  CBC and, 415
  IgE and, 794
Basophilic leukemia, 1376
  gastric acid stimulation test and, 672
Basophilic stippling, 417, 1145, 1146
Batteries, lead in, 858
BE. *See* Barium enema (BE).
Beckwith-Wiederman syndrome, 384
Bell's palsy, EMG and, 595
Bence Jones protein, 1100
Benign prostatic hypertrophy (BPH)
  cystoscopy for, 549
  PAP levels in, 4
  PSA and, 1090
  ultrasonography for, 1293
Benzene toxicity, 1052
Benzodiazepine abuse, 570–571, 572
Beriberi
  EMG and, 595
  vitamin B_1 and, 1370
Bernard-Soulier syndrome
  bleeding time and, 258
  MPV and, 1037
  platelet count and, 1038
Bernstein test (acid perfusion), 613–616
Berylliosis, calcium and, 306
Beta cell failure, insulin response test and, 807
Beta cell transplantation, C-peptide levels in, 491
Beta-blockers, stress testing and, 632
Bethesda System, Pap smear and, 1000
BGP (bone GLA protein), 986–988
Bicarbonate, 262, 263, 264, 266
  antidepressant toxicity and, 151
  PTH and, 1004
Biclonal gammopathy, IFE and, 792
Bicornuate uterus, hysterosalpingography of, 788
Bile duct(s)
  cholangiography of, 367–370
  CT of, 422, 430, 461
  ERCP of, 37–374
  hepatobiliary scan of, 753–757
  PTC of, 363
  ultrasonography of, 1272–1275
Bile duct cysts, PTC of, 364
Bile duct obstruction
  amylase levels in, 63
  hepatobiliary scan for, 754
  radiofrequency ablation and, 1126
  ultrasonography for, 11261273
Bile salt deficiency, fecal fat and, 638
Biliary atresia
  ALP levels in, 30
  hepatobiliary scan for, 754
  vitamin E, 1365
Biliary cirrhosis. *See also* Cirrhosis.
  ceruloplasmin and, 346
  copper and, 484
  HDLC and, 376
  osteocalcin and, 987
  primary, antimitochondrial antibodies and, 135
Biliary enteric bypass patency, hepatobiliary scan and, 754
Biliary fistula, hepatobiliary scan and, 754
Biliary leak, hepatobiliary scan and, 754
Biliary sclerosis, PTC of, 363
Biliary system
  cholangiography of, 363–366
  CT of, 429–433
  ultrasonography of, 1272–1275
Biliary tract disease
  bilirubin and, 197
  oxalate and, 994
Biliary tract obstruction
  ALP levels in, 30
  ALT levels in, 16
  AST levels in, 180
  bilirubin and, 197
  GGT and, 705
  HP and, 723
  PT and, 1105
Biliary tract radionuclide scan. *See* Hepatobiliary scan.

Bilirubin, 196–199
amniotic fluid analysis and, 58–59
urinary, 1331, 1332
Bing test, 1250, 1251
Binocularity, VER and, 628
Biomicroscopy, slit-lamp, 1182–1185
Biopsy. *See also specific type, e.g.,* Fine-needle aspiration biopsy.
bladder, 200–203
bone, 203–206
bone marrow, 206–211
breast, 211–214, 758–759, 1194–1198
cervical, 215–218, 404–407
chorionic villus, 218–222
endometrial, 404–407
endoscopic, 224, 617
intestinal, 222–225
laparoscopic
of cancerous tumors, 848, 852
of ovary, 852
liver, 229–232
lung, 233–237
lymph node, 238–241
muscle, 241–245
prostate, 245–248
renal, 225–229
skin, 248–251
thyroid, 251–255
Biopsy site, PET and, 1065
Biparietal diameter, ultrasonography of, 1279
Bipolar disorder, 150
Birth weight, AFP and, 647
2,3-Bisphosphoglycerate, 1025, 1029
Bitter taste, GER and, 681
Black feces, analysis of, 635
Bladder
biopsy of, 200–203
cystometry of, 544–545
cystoscopy of, 548–549
IVP of, 817–821
KUB study of, 834
normal capacity of, 545
ultrasonography of, 1262–1265
voiding cystourethrography of, 551–555
Bladder calculi
CT of, 452
cystoscopy of, 549
IVP of, 818
retrograde ureteropyelography and, 1163
Bladder cancer
calcium and, 313
CK and, 497
cystoscopy for, 548
MRI of, 908, 933
ultrasonography of, 1263
urine markers of, 255–257
Bladder diverticulum, ultrasonography of, 1263
Bladder fullness
inability to perceive, 545
normal sensation of, 545
Bladder function, urodynamic testing of, 544–547
Bladder injury, voiding cystourethrography for, 552
Bladder paralysis, 545
Bladder pressure, normal, 545
Bladder rupture/perforation, peritoneal fluid analysis and, 1022
Bladder tumor(s)
IVP of, 818
ultrasonography of, 1263, 1286
Bladder tumor antigen (BTA), 256
Blastocystis, 991
Blastomycosis, bronchoscopy for, 289
Blebs, pulmonary angiography of, 89
Bleed localization study, gastrointestinal, 685–689
Bleeding. *See also* Blood loss; *at specific site, e.g.,* Gastrointestinal bleeding.
A/G ratios and, 20
APTT and, 1011
barium enemas and, 189
bone marrow biopsy and, 208
CSF analysis and, 342
CT for
angiographic, 426
cerebral, 435
pancreatic, 448
pituitary, 457
renal, 461
ECG and, 587
FDP and, 650
fecal analysis and, 635
fetal-maternal, Kleihauer-Betke test for, 836
fibroids and, 1338
gonioscopy and, 711
Hcr and, 728
Hgb and, 734
lactic acid and, 843
laparoscopic detection of, 849
liver-spleen scan of, 873
MRI of, 908, 929, 933, 939
obstetric ultrasonography of, 1279
p-ANCA and, 115
pelvic ultrasonography for, 1286
platelet count and, 1037, 1038
proctosigmoidoscopy and, 1080
PT and, 1104
radiofrequency ablation and, 1126
RBC count and, 1136

Bleeding (*Continued*)
vitamin E and, 1365
vitamin K and, 1367
WBC count and, 1376
Bleeding disorders
angiography of, 70, 75, 80, 85, 89
coagulation factors and, 390
natural products and nutraceuticals affecting, 1429–1430
Bleeding sites
colonoscopy for, 399
cystoscopy for, 548
Bleeding time, 257–259
Blepharitis, slit-lamp biomicroscopy of, 1183
Blepharochalasis, VF testing and, 1357
Blighted ovum, ultrasonography of, 1279
Blind loop syndrome, folate and, 659
Blinking, 1174
Blood
amino acid screening of, 42–46
β_2-M and, 962, 963
CA 125 in, 296
calcium in, 304–308
catecholamines in, 330–334
chloride in, 354–358
chromosome analysis of, 383–386
creatinine in, 499–502
fecal. *See* Feces, blood in.
fungal culture of, 539
IFE of, 791–793
incompatibility of. *See* Transfusion reaction(s).
iron-binding capacity of, 1234
ketones and, 828–833
magnesium and, 896–899
osmolality of, 980–983
oxygen-combining capacity of, 733
phosphorus and, 1025–1028
potassium in, 1068–1072
protein in, 1091–1094
transfusion of. *See* Transfusion(s).
uric acid in, 1322–1325
viral culture of, 541–544
Blood clot (clotting). *See also* Coagulation.
cystoscopy of, 548
MRI of, 908, 933
retraction of, 288, 386–388
retrograde ureteropyelography of, 1164
vs. venous obstruction, 1348
Blood collection equipment, 1409
Blood culture, 520–524
Blood dyscrasias
RBC count and, 1135
RBC indices and, 1141
RBC morphology and, 1146
WBC count and, 1376
Blood flow
carotid ultrasonography of, 1254
lower extremity ultrasonography of, 1256–1257
MI scan of, 967
MRA of, 904
MRI of, 912, 917, 939
obstructed, CSF analysis in, 342
PET and, 1056, 1061, 1065
plethysmography and, 1043
venous ultrasonography of, 1306
Blood gases, 260–271. *See also specific gas.*
A/a gradient and a/A ratio and, 36
acid-base imbalance in, 264–267
arterial, 269–270, 1113
pulse oximetry and, 1117
capillary, 270
pH of, 260
scalp sample of, 270
SI units of, 261–262
umbilical cord, 270
venous, 270
Blood groups and antibodies, 272–276
Blood loss. *See also* Bleeding.
A_{1c} and, 708
anemia from, 1338
CBC and, 418
CK and, 497
Hcr and, 728
Hgb and, 733
iron and, 824, 825
reticulocyte count and, 1161
Blood loss scan, gastrointestinal, 685–689
Blood pool imaging, 276–280
Blood pressure
high. *See also* Hypertension.
CT cardiac scoring for, 439
monitoring of, 586
ultrasonography and, 1290
Blood smears, 1146
Blood specimens
collection equipment and, 1409
collection of, 1404–1406
collection procedure for, 1409–1412
order of draw for, 1412–1413
site selection for, 1406–1409
Blood sugar. *See* Glucose.
Blood urea nitrogen (BUN), 1313–1316
CK and, 500
Blood vessels
CT of, 425–429
lower extremity ultrasonography of, 1257
MRA of, 904
Blood-borne pathogens
CDC Isolation Precautions and, 1434–1435
OSHA standards and, 1438–1451

Blurred vision, 1357
BMD (bone mineral densitometry), 280–283
BNP (B-type natriuretic peptide), 293–295
Body fluid(s)
  collection of, 1415
  phosphorus in, 1025
  viral culture of, 541–544
Body plethysmography, 1042, 1043, 1045, 1113
Body Substance Isolation, 1442
Bone(s)
  ALP levels in, 28–29
  biopsy of, 203–206
  MRI of, 925
  phosphorus in, 1025, 1028–1029
  radionuclide scan of, 284–287
  x-ray of, 1129–1131
  zinc in, 1384
Bone anomalies, x-ray of, 1129
Bone cancer
  calcium and, 305, 314
  ceruloplasmin and, 346
  metastatic
    PAP levels in, 4
    phosphorus and, 1026
  osteocalcin and, 986
Bone cyst, MRI of, 924
Bone deformity, x-ray of, 1129
Bone degeneration, x-ray of, 1129, 1130
Bone disease
  ALP levels in, 30
  APL in, 30
  chest x-ray of, 349
  osteocalcin and, 986
  scan for, 284
  urine calcium and, 313
  vitamin D and, 1362
Bone fracture, x-ray of, 1129
Bone GLA protein (BGP), 986–988
Bone infarcts, MRI of, 925
Bone marrow
  biopsy of, 206–211
  iron in, 824
  MRI of, 925
  RBC production in, 1135
Bone marrow depression, WBC count and, 1376, 1377
Bone marrow failure
  parvovirus B19 and, 1014
  RBC count and, 1135, 1136
  WBC count and, 1377
Bone marrow hyperplasia, Hcr and, 728
Bone marrow replacement
  platelet count and, 1038
  reticulocyte count and, 1161
Bone metabolism, osteocalcin and, 986
Bone metastasis
  PAP levels in, 4
  phosphorus and, 1026
Bone mineral densitometry (BMD), 280–283
Bone necrosis, scan for, 285
Bone pain, scan for, 284
Bone spurs, x-ray of, 1129, 1130
Bone tumor, MRI of, 924
Borrelia burgdorferi, 890
Botulism, 530
Bowel. *See also* Intestinal *entries;* Intestine(s); *specific part.*
Bowel carcinoma, ADH levels in, 153
Bowel damage, radiofrequency ablation and, 1126
Bowel disease, oxalate and, 994
Bowel distention, colonoscopy and, 399
Bowel infection, colonoscopy and, 399
Bowel obstruction, KUB study of, 834
Bowel perforation/rupture
  ALP levels in, 30
  barium enema and, 189
  CT of, 422
Bowel resection
  laparoscopic, 848
  vitamin D and, 1362
BPH. *See* Benign prostatic hypertrophy (BPH).
Bradyarrhythmias, Holter monitor and, 764
Bradycardia
  exercise stress test and, 632
  Holter monitor and, 764
  magnesium and, 898
  potassium and, 1070
Brain. *See also* Cerebral; Cerebro- *entries.*
  acetylcholinesterase in, 1132
  CT of, 434–438, 456–460
  EEG of, 590–593
  evoked potentials of, 627–630
  MRI of, 911–915, 936–939
  PET of, 1055–1059
Brain cancer, EEG for, 591
Brain damage
  amino acid blood screen of, 44
  ERP and, 628
Brain death, EEG for, 591
Brain disease, degenerative, CSF analysis and, 342
Brain infarction
  CK and, 497
  CT of, 435
  EEG of, 591
  MRI of, 912, 913
  TG and, 1237

Brain injury
CSF analysis in, 342
SER and, 628
Brain tumors
ADH levels in, 153
carbon dioxide and, 323
MRI of, 912
VF testing and, 1357
Brainstem auditory evoked potentials (BAEPs), 627–630
Brainstem auditory evoked responses (BAERs), 627–630
Brainstem lesions, ABR and, 628
Branched-chain ketonuria, 830
BRCA1 gene, 916
BRCA2 gene, 916
Breast
biopsy of, 211–214, 758–759, 1194–1198
mammogram of, 940–943
MRI of, 916–919
observable changes in, 1195
ultrasonography of, 1265–1268
Breast abscess
mammogram of, 940, 941
MRI of, 917
ultrasonography of, 1266
Breast anomalies, MRI of, 917
Breast biopsy, 211–214
needle, 213, 758–759
open, 213, 758, 759
stereotactic, 1194–1198
Breast calcifications, mammogram of, 941
Breast cancer
β_2-M and, 961
CA 15–3 in, 298
CA 125 in, 296
calcitonin and calcitonin stimulation tests for, 302
calcium and, 313
CEA and, 329
estrogen and progesterone receptor assays for, 623–624
ferritin and, 641
HER-2/Neu oncoprotein and, 757
mammogram for, 941
MRI of, 916, 917
stereotactic biopsy for, 1195
ultrasonography of, 1266
Breast cancer gene, 916
Breast cyst
mammogram of, 940, 941
MRI of, 917
ultrasonography of, 1266
Breast disease
CEA and, 329
mammogram for, 941
Breast hematoma, mammogram of, 941
Breast implant, MRI of, 916
Breast implant rupture, MRI of, 917
Breast mass/tumor
mammogram of, 940, 941, 1195
TSH-producing, 1218
ultrasonography of, 1266
Breast milk, IgA in, 797
Breast milk jaundice, bilirubin and, 197
Breast pain, mammogram for, 941
Breastfeeding, prolactin and, 1087
Breech position, ultrasonography of, 1279
Bronchial anomalies, CT of, 474
Bronchial carcinoid tumor, 12
Bronchial carcinoma, 5-HIAA and, 783
Bronchial diverticulum, 288
Bronchial provocation, 1113
Bronchial stenosis, 289
Bronchial tree, bronchoscopy of, 287–293
Bronchiectasis
Mycobacterium culture and smear for, 510
PFTs and, 1115
Bronchitis
ACE levels in, 98
blood gases and, 265
carbon dioxide and, 323
chest x-ray for, 349
lung perfusion scan of, 878
lung ventilatory scan of, 882
PFTs and, 1115
plethysmography and, 1042
throat culture for, 533
viral culture for, 541
Bronchoconstriction, blood gases and, 265
Bronchodilators, PFTs and, 1113
Bronchogenic carcinoma
bronchoscopy for, 288, 289
lung ventilatory scan of, 882
mediastinoscopy of, 948
Bronchopulmonary aspergillosis, IgE and, 794
Bronchoscopy, 287–293
fiberoptic, 291
lung biopsy and, 235–236
Mycobacterium culture and smear and, 512, 513
pulse oximetry and, 1117
rigid, 291
sputum cytology and, 558
sputum smear and, 526, 527
Bronchospasm
A/a gradient, a/A ratio and, 36
hypersensitivity pneumonitis serology and, 785
Bruises, vitamin K and, 1367
BTA (bladder tumor antigen), 256

B-type natriuretic peptide (BNP), 293–295
Budd-Chiari syndrome, liver-spleen scan of, 873
Bulimia nervosa, 150
Bullae, pulmonary angiography of, 89
Bullets, lead in, 858
Bullous keratopathy, pachymetry and, 997
BUN. *See* Blood urea nitrogen (BUN).
Bundle-branch block
  ECG and, 587
  exercise stress test and, 632
Burkitt's lymphoma

Feminization disorders, estradiol and, 621
Femoral head, MRI of, 924, 925
Femur, RBC production in, 1135
FEP (free erythrocyte protoporphyrin), 605–607
Ferritin, 640–643, 824
Fertility
pelvic ultrasonography and, 1286
semen analysis and, 1177
uterine fibroid embolization and, 1338
Fetal age sonogram. *See* Obstetric ultrasonography.
Fetal anomalies
chorionic villus biopsy for, 219
ultrasonography and, 1279
Fetal death
AFP and, 647
cardiolipin antibodies and, 131
FDP and, 650
lupus anticoagulant antibodies and, 885
ultrasonography of, 1279
Fetal distress
AFP and, 647
L/S ratio and, 861
Fetal fibronectin (fFN), 643–645
Fetal gestational age
AFP and, 647
ultrasonography and, 1279
Fetal hemoglobin, 836–838
hereditary persistence of, 738
Fetal hydrops, ultrasonography of, 1279
Fetal lung maturity, L/S ratio and, 861
Fetal malpresentation, ultrasonography of, 1279
Fetal position, ultrasonography of, 1279
Fetal Rh incompatibility, ultrasonography and, 1279
Fetal scalp sampling, 1408
Fetal transfusion, ultrasonography and, 1279
Fetal-maternal hemorrhage, Kleihauer-Betke test for, 836
α_1-Fetoprotein (AFP), 645–649
amniotic fluid analysis and, 58, 59
Fetus, amniotic fluid analysis and, 58
FEV (forced expiratory volume), 1112
Fever
acetaminophen/acetylsalicylic acid for, 66
A/G ratios and, 20
amino acid blood screen in, 44
blood culture for, 521, 523
blood gases and, 265, 266
carbon dioxide and, 323
hyaline casts in, 1334
infectious mononucleosis and, 804
Lyme disease and, 890
serum sodium and, 1186
urine porphyrins and, 1052
viral culture for, 542
Fever of unknown origin
gallium scan for, 669
WBC scan for, 1381
fFN (fetal fibronectin), 643–645
Fiberoptic bronchoscopy, 291
Fibrin
APTT and, 1011
plasminogen and, 1032
Fibrin breakdown products (FBP), 650–652
Fibrin degradation products (FDP), 650–652
Fibrin split products (FSP), 650–652
Fibrinogen, 652–655
APTT and, 1010
clot retraction and, 387
degradation of, 1011, 1032
disorders of, bleeding time and, 258
Fibrinolysis, fibrinogen and, 653
Fibrinolytic therapy, 650, 1032
Fibroadenolipoma, breast ultrasonography for, 1266
Fibroadenoma, breast ultrasonography for, 1266

Fibroid (leiomyoma)
embolization of, 1337–1342
hysterosalpingography for, 788
laparoscopy for, 852, 853
MRI of, 933
pelvic CT for, 452
pelvic ultrasonography for, 1286
Fibroma, skin biopsy for, 249
Fibronectin, fetal, 643–645
Fibrosarcoma
glucose and, 694
MRI of, 925
Fibrosis
breast ultrasonography for, 1266
lung biopsy for, 233
pancreatic, ERCP and, 371
plethysmography and, 1042
pulmonary. *See* Pulmonary fibrosis.
thyroid scan and, 1214
Fifth disease (erythema infectiosum), parvovirus B19 and, 1014
Filter paper test, 1218, 1219
Fine-needle aspiration biopsy
breast ultrasonography for, 1266
of bone marrow cells, 209
pancreatic ultrasonography for, 1283
parathyroid ultrasonography for, 1303
prostatic ultrasonography for, 1293
scrotal ultrasonography for, 1296
Finger pressure, plethysmography and, 1042
Fingertips, pulse oximetry of, 1117
First morning urine collection, 1413
FISH (fluorescent in situ hybridization), 383
Fish eye disease, HDLC and, 376
Fish infestation, vitamin B_{12} and, 1360
Fissure(s)
anal, 635
proctosigmoidoscopy and, 1080
Fistula(s)
A/G ratios and, 20
arteriovenous. *See* Arteriovenous fistula.
barium enema and, 189
barium swallow and, 193
CTA of, 426
cystoscopy for, 549
GI blood loss scan and, 685
hepatobiliary scan and, 754
hysterosalpingography and, 788
potassium and, 1070
proctosigmoidoscopy and, 1080
renogram of, 1157
retrograde urethrography of, 1319
Five-hour glucose tolerance test, 807
Flaccid bladder, 545
Flank pain, bladder ultrasonography and, 1263
Flecainide, 104–110
Flexible bronchoscopy, 287–293
Flexible fiberoptic endoscope, for proctosigmoidoscopy, 1080
Flexible fiberoptic sigmoidoscopy. *See* Proctosigmoidoscopy.
Flexible proctosigmoidoscopy. *See* Proctosigmoidoscopy.
Flow-volume loops, 1112, 1113
Fluid(s)
CBC and, 418
loss of, magnesium and, 897
lung displacement by, perfusion scan of, 878
sterile, bacterial culture and, 516, 517, 519
total protein and, 1093
Fluid balance/imbalance
calcium and, 305
chloride and, 355
Hcr and, 728
Hgb and, 733
urinalysis and, 1331
Fluid retention
Hcr and, 728
Hgb and, 734
Fluorescein angiography (FA), 655–658
Fluorescent in situ hybridization (FISH), 383
Fluorescent treponemal antibody testing (FTA-ABS), 1203–1205
Fluorodeoxyflucose (FDG), PET and, 1055, 1060, 1064
Fluorosis, PTH and, 1004
Flushing, antidepressant toxicity and, 151
Focal radionuclide uptake, PET and, 1065
Focal seizures
EEG and, 591
PET and, 1056
Folate (folic acid), 659–661
homocysteine and, 766–767, 767
Folate (folic acid) deficiency, 208, 767
ALP levels in, 30
amino acid screen in, 49
platelet count and, 1038
RBC indices and, 1141
RBC morphology and, 1146
RBCs and, 1135
uric acid and, 1326
WBC count and, 1377
Folex. *See* Methotrexate.
Follicle(s), ultrasonography of, 1286
Follicle-stimulating hormone (FSH), 661–664, 888, 1084
Follitropin. *See* Follicle-stimulating hormone (FSH).

Foot (feet)
venipuncture of, 1408
x-ray of, 1129–1131
Forced expiratory volume (FEV), 1112
Forced inspiratory flow rate, 1112
Forced vital capacity in 1 second (FVC_1), 1112
Foregut carcinoid tumors, 5-HIAA and, 783
Foreign body(ies)
barium swallow and, 193
bronchoscopy and, 288, 289
chest x-ray of, 349
colonoscopy and, 399
hysterosalpingography of, 788
otoscopy and, 989
skeletal x-ray of, 1130
slit-lamp biomicroscopy of, 1183
Foreign surface contact, platelet count and, 1038
Fracture(s)
arthrogram of, 174
arthroscopy of, 177
bone mineral densitometry and, 281
bone scan for, 284, 285
chest x-ray of, 349
CT of, 461
MRI of, 925
vertebroplasty and, 1352–1353
x-ray of, 1129, 1130
FRC (functional residual capacity), 1112
Free calcium. *See* Calcium, ionized.
Free erythrocyte protoporphyrin (FEP), 605–607
Free thyroxine (FT_4), 1226–1228
Free triiodothyronine (FT_3), 1239–1241
Fructosamine, 664–666
Fructose intolerance
ALD levels in, 23
amino acid screen in, 44, 49
hereditary, glucose and, 694
FSH. *See* Follicle-stimulating hormone (FSH).
FSP (fibrin split products), 650–652
FT_3. *See* Free triiodothyronine (FT_3).
FT_4. *See* Free thyroxine (T_4).
FTA-ABS. *See* Fluorescent treponemal antibody testing (FTA-ABS).
Fuchs endothelial disorders, 711
Fuchs endothelial dystrophy, 997
Fucosidosis, sweat chloride and, 359
Full colonoscopy, 398–402
Functional incontinence, 544
Functional residual capacity (FRC), 1112
Fundus photography, 666–668
Fungal culture, 538–541
Fungal infections
lymph node biopsy for, 238
muscle biopsy for, 242
sputum cytology and, 555, 556
Fungal pericarditis, 1017
FVC_1 (forced vital capacity in 1 second), 1112

G

G6PD. *See* Glucose-6-phosphate dehydrogenase (G6PD).
G6PDD. *See* Glucose-6-phosphate dehydrogenase deficiency (G6PDD).
Gadopentetate dimeglumine, in MRI, 908, 912, 916, 924, 928, 932
Galactocele, breast ultrasonography for, 1266
Galactography, 1266
Galactorrhea, prolactin and, 1087
Galactorrhea-amenorrhea syndrome, progesterone and, 1085
Galactosemia
ALP levels in, 30
amino acid screen in, 49
glucose and, 694
liver biopsy for, 229
Gallbladder
abdominal laparoscopy of, 848–849
cholangiography of, 367–370
CT of, 422, 430, 461
ERCP of, 370–374
gangrenous, laparoscopic detection of, 849
PTC of, 363
ultrasonography of, 1272–1275
Gallbladder cancer
CA 19–9 in, 300
PTC of, 364
ultrasonography of, 1273
Gallbladder disorders, hepatobiliary scan for, 754
Gallbladder inflammation
radiofrequency ablation and, 1126
ultrasonography for, 1272, 1273
Gallbladder scan. *See* Hepatobiliary scan.
Gallium scan, 284, 669–671, 1381
Gallstones
CT of, 422, 430
hepatobiliary scan for, 754
PTC of, 363, 364
ultrasonography of, 1272, 1273
Gammopathy(ies)
IFE and, 792
IgA, 798
IgG, 798
monoclonal. *See* Monoclonal gammopathy(ies).
total protein and, 1093

Ganglioblastoma
  catecholamines and, 331, 335
  HVA and, 770
Ganglion cyst, arthroscopy of, 176
Ganglion nerve cells, of retina, 977–978
Ganglioneuroma
  catecholamines and, 331, 335
  metanephrines and, 952
  VMA and, 1343
Gangrene, ALD levels in, 22
Gangrenous gallbladder, laparoscopic detection of, 849
Gantry, CT and, 421, 425, 430, 434, 439, 442, 447, 451, 456, 460, 465, 469, 474
Gardnerella vaginitis, 1333
Gasoline, lead in, 858
Gastrectomy, GTT and, 701
Gastric acid
  chloride and, 355
  reflux of. *See* Gastroesophageal reflux (GER).
  stimulation test for, 672–675
Gastric cancer
  CA 19–9 in, 300
  capsule endoscopy for, 319
  CEA and, 329
  ceruloplasmin and, 346
  CK and, 497
  gastric acid stimulation test for, 672, 673
  gastrin stimulation test for, 679
  GH tests and, 718
  glucose and, 694
  H. pylori and, 725
  hexosaminidase and, 762
  UGI series and, 1310
Gastric emptying
  rate of, 676
  scan of, 675–678
Gastric lavage
  antiarrhythmic toxicity and, 107
  antidepressant toxicity and, 151
  antipsychotic toxicity and, 159
  methemoglobin and, 955
Gastric mucosa, Meckel's diverticulum scan of, 943, 944
Gastric outlet obstruction, EGD and, 617
Gastric outlet syndrome, gastric emptying scan and, 676
Gastric perforation/rupture
  capsule endoscopy for, 319
  UGI series and, 1310
Gastric polyps
  gastric acid stimulation test for, 673
  UGI series and, 1310
Gastric radiography. *See* Upper gastrointestinal series (UGI).
Gastric resection, amylase levels in, 63
Gastric suctioning, blood gases and, 266
Gastric surgery, vitamin B_{12} and, 1360
Gastric tumors, UGI series and, 1310
Gastric ulcer
  capsule endoscopy for, 319
  EGD and, 617
  gastric acid stimulation test for, 673
  gastric emptying scan and, 676
  gastrin stimulation test for, 679
  UGI series and, 1310
Gastrin, 679
Gastrin stimulation test, 678–681
Gastritis
  capsule endoscopy for, 319
  EGD for, 618
  fecal analysis and, 635
  gastric acid stimulation test for, 673
  gastrin stimulation test for, 679
  H. pylori and, 725
  UGI series and, 1310
Gastroenteritis
  barium enema and, 189
  gastric emptying scan and, 676
  viral culture for, 542
Gastroenterostomy, GTT and, 701
Gastroesophageal reflux (GER)
  esophageal manometry for, 613, 614
  gastric emptying scan and, 676
  scanning for, 681–685
  symptoms of, 681
  UGI series and, 1309
Gastrointestinal bleeding
  ammonia and, 55
  BUN and, 1314
  CT of, 421, 422, 452
  EGD of, 617
  fecal analysis for, 635
  Meckel's diverticulum scan of, 943, 944
  scan for, 685–689
Gastrointestinal carcinoma
  CA 19–9 in, 299
  IgA and, 798
  IgM and, 798
  transferrin and, 1234
Gastrointestinal disease
  colonoscopy for, 399
  IgA and, 798
  natural products and nutraceuticals affecting, 1429
  renin and, 1153
  vitamin A and, 1371
  vitamin K and, 1367
Gastrointestinal infarction, CK and, 497
Gastrointestinal irritation, acetaminophen intoxication and, 66

  RBC indices and, 1141
  RBC morphology and, 1146
  TG and, 1237
  total protein and, 1093
  urine sodium and, 1189
  vitamin B_6 and, 1370, 1371
  vitamin B_{12} and, 1360
  vitamin C and, 1370, 1371
  vitamin D and, 1362
  vitamin E and, 1365
  vitamin K and, 1367
  WBC count and, 1376
  zinc and, 1385
Malaria
  blood culture for, 521
  cold agglutinin titer and, 394
  liver biopsy and, 229
  osmotic fragility and, 984
  platelet count and, 1038
  RF and, 1168
  VDRL testing and, 1204
  WBC count and, 1376
Male(s), testosterone in, 1207
Male fertility, semen analysis and, 1177
Male reproductive organs, zinc in, 1384
Malignancy. *See also under specific anatomic site; specific neoplasm.*
  abdominal CT of, 421
  ADH levels in, 153
  ALD levels in, 22
  angiographic CT of, 426
  biliary/liver CT of, 430
  bladder biopsy for, 200–203
  bladder ultrasonography and, 1263
  bone biopsy for, 203–206
  bone marrow biopsy for, 206–211
  breast biopsy for, 211–214
  BUN and, 1314
  C3 complement and, 409
  C4 complement and, 409
  calcium and, 305
  CBC and, 418
  cerebral CT of, 435
  cervical biopsy for, 215–218
  chorionic villus biopsy for, 218–222
  colonoscopy and CT of, 443
  copper and, 484
  creatinine clearance and, 504
  echocardiography of, 579
  eosinophil count in, 603
  ESR in, 608
  fibrinogen and, 653

Malignancy (*Continued*)
folate and, 660
globulin proteins in, 1093
Hcr and, 728
Hgb and, 733, 734
HP and, 723
intestinal biopsy for, 222–225
laparoscopic biopsy of, 848, 852
laparoscopic findings of, 849
liver biopsy for, 229–3232
lung biopsy for, 233–237
lung perfusion scan of, 878
lymph node biopsy for, 238–241
muscle biopsy for, 241–245
Mycobacterium culture and smear for, 510
ocular, gonioscopy and, 711
pancreatic CT of, 448
pelvic CT of, 452
pelvic ultrasonography for, 1286
pelvic ultrasonography of, 1286
pericardial fluid analysis and, 1017
peritoneal fluid analysis and, 1022
PET and, 1065
pituitary CT of, 456, 457
platelet count and, 1038
pleural fluid analysis and, 1048
prostate biopsy for, 245–248
PTH and, 1004
RBC count and, 1135
RBC indices and, 1141
RBC morphology and, 1146
renal biopsy for, 225–229
renal CT of, 461
renogram and, 1157
renogram of, 1157
retrograde ureteropyelography and, 1164
skin biopsy for, 248–251
spinal CT of, 465
splenic CT of, 470
sputum cytology and, 556
thyroid biopsy for, 251–255
TIBC and, 828
total complement and, 411
total protein and, 1093
transferrin and, 1234
UGI series and, 1310
uric acid and, 1323, 1326
urine cytology and, 560
urine protein and, 1100
VDRL testing and, 1204
Viral hepatitis, VDRL testing and, 1204
vitamin C and, 1371
WBC count and, 1376
x-ray of, 1130
Malignant hypertension, renin and, 1153
Malignant hyperthermia
CK and, 497
myoglobin and, 976
Malignant melanoma
IgD and, 798
skin biopsy of, 249
Mallory-Weiss syndrome
capsule endoscopy for, 319
EGD and, 618
Mallory-Weiss tears, fecal analysis and, 635
Malnutrition. *See also* Nutritional deficiency.
A/G ratios in, 20
amino acid blood screen in, 44
Apo B and, 171
α_1-AT and, 165

Manic-depressive disorders, catecholamines and, 331, 335
Manometry, esophageal, 613–616
Mantoux skin test, 349, 1246–1249
Maple syrup urine disease
amino acid screen in, 49
glucose and, 694
Marburg virus, viral culture and, 542
Masculinization, testosterone and, 1207
Masks, CDC Isolation Precautions and, 1433, 1436
Mast cells, IgE and, 794
Mastectomy
mammogram after, 941
MRI after, 917
Mastitis, 1266
mammogram for, 941

Mastocytosis
5-HIAA and, 783
gastric acid stimulation test and, 673
Maternal age, advanced, L/S ratio and, 861
Maternal blood
AFP and, 645–646, 647
Hgb electrophoresis and, 738
Maternal diabetes, L/S ratio and, 861
Maternal-fetal Rh incompatibility, 481
Maturation, sexual, FSH and, 662
Maximal expiratory flow, 1112
Maximal inspiratory-expiratory pressures, 1112
Maximal voluntary ventilation, 1112
May-Hegglin anomaly
MPV and, 1037
platelet count and, 1038
MB. *See* Myoglobin (MB).
MCH (mean corpuscular hemoglobin), 1140. *See also* Red blood cell (RBC) indices.
MCHC. *See* Mean corpuscular hemoglobin concentration (MCHC).
MCV (mean corpuscular volume), 1140. *See also* Red blood cell (RBC) indices.
Hgb and, 736
Mean corpuscular hemoglobin (MCH), 1140. *See also* Red blood indices.
Mean corpuscular hemoglobin concentration (MCHC), 735, 736, 1140. *See also* Red blood cell (RBC) indices.
Mean corpuscular volume (MCV), 1140. *See also* Red blood cell (RBC) indices.
Hgb and, 736
vitamin B_{12} deficiency and, 1359
Mean platelet volume (MPV), 1037
Measles, 1172–1173
VDRL testing and, 1204
Measles serology, 1172–1174
Measles virus, viral culture and, 541, 542
Meckel's diverticulum scan, 943–947
Meconium, 59
Mediastinal lymphadenopathy, CT of, 474
Mediastinal tumor
chest x-ray of, 349
CT of, 474, 475
thyroid scan and, 1214
Mediastinoscopy, 947–951
Mediastinum, mediastinoscopy of, 947–951
Medical records, OSHA standards for, 1448–1449
Medullary breast carcinoma, ultrasonography for, 1266
Medullary thyroid carcinoma, calcitonin and calcitonin stimulation tests for, 302
Megakaryocyte(s), 1036
bone marrow biopsy and, 208
Megakaryocytic hypoproliferation, platelet count and, 1038
Megaloblastic anemia
folate and, 659, 660
hemosiderin and, 741
Hgb electrophoresis and, 738
IF antibodies and, 822
LDH and, 840
platelet count and, 1038
RBC cholinesterase and, 1133
reticulocyte count and, 1161
vitamin B_{12} and, 1360
Melanoma
gallium scan of, 669
malignant. *See* Malignant melanoma.
Membranous glomerulonephritis, total complement and, 412
Meningioma
MRI of, 913, 939
pituitary CT of, 457
Meningitis
blood culture for, 523
C4 complement and, 409
CSF analysis and, 342
EEG and, 591
tuberculous, ADH levels in, 153
viral culture for, 542
Meningocele, CT of, 465, 466
Meningoencephalitis, Alzheimer's disease markers in, 40
Meniscal injury, arthroscopy of, 176
Meniscal tears
arthrogram of, 174
MRI of, 925
Menkes disease
ceruloplasmin and, 346
copper and, 484
Menopause
FSH and, 662
LH and, 888
Menorrhagia
APTT and, 1011
platelet count and, 1037
PT and, 1104
Menotropin therapy, estradiol and, 621
Menstrual cycle
ACTH levels in, 13
AT-III and, 162
CA 125 in, 296
estradiol and, 621, 622
FSH and, 662
LH and, 888
Menstruation, WBC count and, 1376

Mental status changes
anticonvulsant toxicity and, 143
digoxin toxicity and, 107
Mercury poisoning, β_2-M and, 961
Metabolic acidosis
acetaminophen intoxication and, 66
blood gases and, 266
carbon dioxide and, 323
chloride and, 355, 356
magnesium, 898
serum sodium and, 1186
Metabolic alkalosis
blood gases and, 266–267
carbon dioxide and, 323
Metabolic disturbances
in utero, chorionic villus biopsy for, 219
skeletal x-rays and, 1130
transfusion-related, 1424
uric acid and, 1326
vitamin C and, 1370
Metabolic syndrome. *See* Syndrome X.
Metachronous lesions, CT colonoscopy for, 443
Metal poisoning, 858
Metanephrines, 951–954
Metastatic disease
abdominal CT of, 421, 422
APF and, 647
biliary/liver CT of, 430
bone
calcium and, 313, 314
PAP levels in, 4
bone scan for, 284, 285
breast, HER-2/Neu oncoprotein and, 757
calcium and, 306
chest x-ray of, 349
CNS, CSF analysis in, 342
colosnoscopy and CT of, 443
hepatic ultrasonography of, 1272, 1273
liver-spleen scan of, 873, 874
lymph node biopsy for, 238
lymphangiogram of, 893
MI scan and, 967
MRI of, 913, 929, 937
osteocalcin and, 986
pancreatic CT of, 448
Pap smear and, 1001
pelvic CT of, 452
pelvic ultrasonography for, 1286
PET and, 1056, 1065
phosphorus and, 1026
pituitary CT of, 457
platelet count and, 1038
radiofrequency ablation for, 1125
RAIU and, 1122
RBC morphology and, 1146
renal CT of, 461
splenic CT of, 470
thoracic CT of, 474, 475
thyroglobulin and, 1210
thyroid scan and, 1214
Methanol poisoning, serum osmolality and, 981
Methemoglobin (MetHb), 954–956
Methemoglobinemia, 954, 955
Methionine, 43, 48
Methionine challenge test, 767
Methods of control, OSHA standards for, 1442
Methotrexate, 800–804
administration of, 800
dosage of, 801
toxic levels of, 802
Methylene blue, 955
Methylhistidine, 43, 48
Methylmalonic acid, 766–769
Methylmalonic aciduria, ketones and, 830
Metyrapone stimulation test, 10, 11, 13
cortisol and, 486, 487, 488
Mexate. *See* Methotrexate.
Mg^{2+}. *See* Magnesium.

  laparoscopy for, 853
  MRI of, 933
Pelvic pain
  fibroids and, 1338
  laparoscopic evaluation of, 852
Pelvic sonography, 1285–1288
Pelvic vascular disease, MRI of, 933
Pelvic vein compression, plethysmography and, 1043
Pelvis
  abdominal laparoscopy of, 848–851
  CT of, 451–455
  lymph node sonography of, 1275–1278
  MRI of, 932–935
  PET of, 1064–1068
  RBC production in, 1135
  ultrasonography of, 1285–1288
  voiding cystourethrogragphy and, 552
Pelviscopy, gynecologic, 852–855
Pemphigus, skin biopsy of, 249
Penicillin G, IgE and, 795
Pentacarboxylporphyrin, 1051. *See also* Porphyrin(s).
Pentagastrin (Peptavlon) provocation test, 302
Peptic disorders, gastrin stimulation test for, 679

Peptic ulcer disease
A/G ratios in, 20
amylase levels in, 63
differential diagnosis of, 725
fecal fat and, 638
gastric acid stimulation test for, 672
H. pylori and, 725
Peptides, reabsorption of, 704–705
Percutaneous transhepatic cholangiography (PTC, PTHC), 363–366
Percutaneous umbilical cord sampling, 1408
Perforation. *See at anatomic site, e.g.,* Esophageal perforation/rupture.
Perfusion lung scan, radionuclide, 877–881
Periaortic hematoma, MRI of, 921
Pericardial anomalies
MRA of, 904
MRI of, 920
Pericardial effusion
chest x-ray for, 349
echocardiography of, 579
MRI of, 921
transesophageal echocardiography of, 583
Pericardial fluid analysis, 1016–1020
Pericardial hematoma, MRI of, 921
Pericardial mass, MRI of, 920
Pericardial tamponade, echocardiography of, 579
Pericarditis, 1017
AST levels in, 180
chest x-ray for, 349
echocardiography of, 579
EGC of, 587
magnetic resonance imaging OF, 921
MI scan and, 967
viral culture for, 542
Pericardium, 1016
Perimetry. *See* Visual field tests.
Perineal approach, to prostate biopsy, 247
Perineal hypospadias, retrograde urethrography of, 1319
Perineal pain, proctosigmoidoscopy for, 1080
Perinephric abscess, retrograde ureteropyelography of, 1164
Perinuclear antineutrophil cytoplasmic antibody (p-ANCA), 115–117
Periodic paralysis, potassium and, 1070
Peripheral anterior synechiae (PAS), gonioscopy and, 710, 711
Peripheral Doppler ultrasonography, 1289–1292
Peripheral vascular disease, MRA of, 904
Perirectal abscess, ultrasonography of, 1293
Perirectal glands, PSA in, 1089
Perirectal tumor, ultrasonography of, 1293
Perirenal abscess
CT of, 461
ultrasonography of, 1269
Perirenal fluid, ultrasonography of, 1269
Perisellar anomalies, MRI of, 936
Peritoneal fluid analysis, 1020–1024
Peritoneal tumor, MRI of, 933
Peritoneoscopy, 852–855
abdominal, 848–851
Peritonitis
amylase levels in, 63
bacterial, 1022
CA 125 in, 296
MRI of, 933
ultrasonography for, 1286
Periurethral glands, PSA in, 1089
Pernicious anemia
ALP levels in, 30
amino acid screen in, 49
bilirubin and, 197
calcitonin and calcitonin stimulation tests for, 302
esoinophil count in, 603
fecal fat and, 638
folate and, 659
G6PD and, 698
gastric acid stimulation test for, 672, 673
gastrin stimulation test for, 679
hemosiderin and, 741

  serum, 1025–1028
  urine, 1028–1031
Phosphorus metabolism, vitamin D and, 1362
Phosphorylation, oxidative, magnesium and, 897, 900
Phosphoserine, 43, 48
Photography, fundus, 666–668
Photosensitivity, anti-extractable nuclear antigens/antibodies and, 156
Phototherapy, bilirubin and, 197
Phycomycosis, bronchoscopy for, 289
Phyllodes tumor, breast ultrasonography for, 1267
Phylloquinone. *See* Vitamin K.
Physical activity. *See also* Exercise.
  impaired, GTT and, 701
Physiologic jaundice of newborn, bilirubin and, 197
Physostigmine, antidepressant toxicity and, 151
Phytonadione. *See* Vitamin K.
PI (phosphatidyl inositol), 861
Pi phenotype, 164–167
Pica, potassium and, 1070
Pick's disease, Alzheimer's disease markers in, 40
PID. *See* Pelvic inflammatory disease (PID).
Pigmented nevus, skin biopsy of, 249
Pill GI endoscopy, 318–321
Pilocarpine iontophoresis sweat test, 358–362
Pinna, otoscopy and, 989
Pituitary abscess, MRI of, 939
Pituitary aneurysm, MRI of, 939
Pituitary bleeding, CT of, 457
Pituitary cyst, MRI of, 937
Pituitary disorders
  prolactin and, 1087
  TRH stimulation test and, 1222
Pituitary dysfunction, TSH and, 1218
Pituitary failure, RAIU and, 1122
Pituitary fossa, CT of, 457
Pituitary gland
  ADH and, 153
  cortisol and, 12
  CT of, 456–460
  FSH and, 662
  GH and, 718
  LH and, 888, 889
  MRI of, 936–939
Pituitary granuloma, MRI of, 939
Pituitary hemorrhage, MRI of, 939
Pituitary hypofunction, anterior, 662
Pituitary infarct, MRI of, 939
Pituitary macroadenoma, MRI of, 936
Pituitary microadenoma, MRI of, 913, 936
Pituitary stalk surgery, prolactin and, 1087
Pituitary tumors
  gonadotropin-secreting, FSH and, 662
  MRI of, 936
  prolactin and, 1087
PK. *See* Pyruvate kinase (PK).
PKU (phenylketonuria), 5-HIAA and, 783
Placenta, ultrasonography and, 1279
Placenta previa
  L/S ratio and, 861
  ultrasonography of, 1279, 1280
Placental abruption
  FDP and, 650
  ultrasonography of, 1279
Placental infarction
  cardiolipin antibodies and, 131
  L/S ratio and, 861
Placental transport, of IgG, 797
Plague, blood culture for, 521
Plaque
  carotid, ultrasonography, 1254
  CT of, 435, 439
  lower extremity ultrasonography of, 1257
  sclerotic. *See* Multiple sclerosis.

Plasma, cholinesterase in, 1132
Plasma cell(s), increased, bone marrow biopsy and, 208
Plasma protein, increased, ESR in, 608
Plasma renin, 1153
Plasma renin activity (PRA), 1152–1156
Plasmapheresis, pseudocholinesterase and, 1109
Plasminogen, 1032–1033
Plasminogen activator, 1032
Plasmodium, 1145, 1147. *See also* Malaria.
Platelet(s), 1036

Progressive systemic sclerosis antibody, 122–123
Proinsulin C-peptide, 490–493
Proinsulin-secreting tumors, 807
Prolactin, 1086–1089
Prolactin-secreting tumors, prolactin and, 1087
Proline, 43, 48
Prolonged immobilization, total protein and, 1093
Prolonged standing, potassium and, 1070
Propionyl coenzyme A carbohydrate deficiency, 830
Propranolol, antidepressant toxicity and, 151
Prostate
biopsy of, 245–248
cystoscopy of, 548
PSA in, 1089
semen analysis and, 1177
voiding cystourethrography of, 552
Prostate adenocarcinoma, PSA in, 1090
Prostate calcifications, ultrasonography of, 1293
Prostate cancer
ADH levels in, 153
CEA and, 329
cholesterol and, 380
CK and, 497
MRI of, 908, 933
PAP levels in, 4
PSA in, 1090
ultrasonography of, 1293
Prostate ultrasonography, 1292–1295
Prostatectomy, 1090
Prostate-specific antigen (PSA), 4, 1089–1091
Prostatic acid phosphatase (PAP), 3–6
Prostatic hypertrophy
benign. *See* Benign prostatic hypertrophy (BPH).
biopsy for, 245
cystoscopy for, 548, 549
IVP of, 818
PSA and, 1090
retrograde ureteropyelography for, 1164
voiding cystourethrography for, 552
Prostatic infarct
PAP levels in, 5
PSA and, 1090

Prostatitis
PAP levels in, 5
ultrasonography for, 1293
Prosthetic devices, platelet count and, 1038
Prosthetic joint, bone of, 285
Prosthetic valves
echocardiography of, 579
transesophageal echocardiography of, 583
Protective equipment, OSHA standards for, 1445–1446
Protein(s)
Bence Jones, 1100
CSF analysis and, 341, 342
dietary
BUN and, 1314
urea nitrogen and, 1316
total and fractions, 1091–1094
urinalysis and, 1331, 1332
urine: total quantitative and fractions, 1100–1103
Protein C, 1095–1097
activated, 1095
deficiency of, 1095
Protein deficiency
APTT and, 1011
PT and, 1104
Protein depletion, TIBC and, 828
Protein digestion, fecal analysis for, 635
Protein ingestion, BUN and, 1314
Protein loss, transferrin and, 1234
Protein malnutrition
iron and, 825
vitamin A and, 1371
Protein S, 1097–1099
activated protein C and, 1095
deficiency of, 1098
Protein synthesis, 1092, 1100
magnesium and, 897, 900
Protein-losing enteropathy, 1093
Proteinuria, osmolality and, 981
Prothrombin, vitamin K and, 1367
Prothrombin deficiency, 1105
Prothrombin time (PT), 1010
international normalized ratio and, 1103–1107
Protime. *See* Prothrombin time (PT).
Protoporphyria, erythropoietic, FEP and, 606
PRP (progesterone receptor protein) assay, 623–627
Prussian blue stain, 741. *See also* Hemosiderin.
PSA. *See* Prostate-specific antigen (PSA).
Pseudoaneurysm. *See also* Aneurysm.
lower extremity ultrasonography of, 1257
MRI of, 908, 929
Pseudocholinesterase, dibucaine number and, 1108–1110
Pseudocyst(s). *See also* Cyst(s).
abdominal CT of, 422
lipase and, 867
pancreatic CT of, 448
pancreatic ultrasonography of, 1283
peritoneal fluid analysis and, 1022
Pseudogout. *See also* Gout.
arthroscopy for, 176
calcium pyrophosphate crystals and, 1200
PTH and, 1005
synovial fluid analysis and, 1199
Pseudohypoacusis, 1192
Pseudohypoparathyroidism
calcitonin and calcitonin stimulation tests for, 302
calcium and, 310, 314
phosphorus and, 1026, 1029
PTH and, 1005
Pseudomembranous enterocolitis, fecal analysis for, 635
Pseudomonas aeruginosa, 525
Pseudomyxoma peritonei, MRI of, 933
Pseudopregnancy, AFP and, 647
Psittacosis, VDRL testing and, 1204
Psoriasis
DHEAS and, 569
uric acid and, 1324
Psoriatic arthritis, HLA-B27 and, 778
Psychiatric disorders, total T_4 and, 1229
Psychogenic polydipsia, ADH levels in, 153
Psychological incontinence, 544–545
Psychosis
ALD levels in, 22
DHEAS and, 569
ERP and, 628
PET and, 1056
PT. *See* Prothrombin time (PT).
PTC (percutaneous transhepatic cholangiography), 363–366
PTH. *See* Parathyroid hormone (PTH).
PTHC (percutaneous transhepatic cholangiography), 363–366
Ptosis, VF testing and, 1357
PTT (partial thromboplastin time), 1010
activated. *See* Activated partial thromboplastin time (APTT).
Puberty
delayed, 1207
precocious. *See* Precocious puberty.
Pulmonary. *See also* Lung *entries.*
Pulmonary abscess, bronchoscopy for, 288
Pulmonary angiography, 88–92

Pulmonary artery
angiography of, 85
echocardiography of, 579
Pulmonary artery agenesis, MRI of, 921
Pulmonary aspiration, GER scan and, 682
Pulmonary atresia, MRI of, 921
Pulmonary compliance
PFTs and, 1114
plethysmography and, 1042, 1043
Pulmonary disability, PFTs and, 114
Pulmonary disease
Apo B and, 171
bronchoscopy for, 288, 289
calcium and, 306
chest x-ray of, 349
chronic obstructive. *See* Chronic obstructive pulmonary disease (COPD).
degenerative/inflammatory, biopsy for, 233
LDLC and, 376
lung perfusion scan of, 878
PFTs and, 1113
plethysmography and, 1042, 1043
sputum cytology and, 556
sweat chloride and, 359
Pulmonary drug regimes, pulse oximetry and, 1117
Pulmonary edema
A/a gradient, a/A ratio and, 36
blood gases and, 265
CK and, 497
PET and, 1061
Pulmonary effusion
lung perfusion scan of, 878
lung ventilatory scan of, 882
Pulmonary embolism
A/a gradient, a/A ratio and, 36
ALP levels in, 30
angiography of, 89
AT-III and, 162
blood gases and, 265
CK and, 497
ESR in, 608
FDP and, 650
lactic acid and, 843
lung perfusion scan of, 877, 878
lung ventilation scan of, 882
phosphorus and, 1026
ultrasonography of, 1306
venography and, 1348
Pulmonary failure, lactic acid and, 843
Pulmonary fibrosis
A/a gradient, a/A ratio and, 36
ACE levels in, 98
chest x-ray for, 349
EPO and, 611
PFTs and, 1115
plethysmography and, 1042
Pulmonary function, lung perfusion scan of, 878
Pulmonary function tests (PFTs), 1111–1116
Pulmonary gas exchange function, pulse oximetry and, 1117
Pulmonary hemosiderosis, idiopathic, anti-GBM antibodies and, 117
Pulmonary hypertension
BNP and, 294
bronchoscopy and, 289
echocardiography for, 579
lung perfusion scan of, 878
transesophageal echocardiography for, 583
Pulmonary infarction
ALP levels in, 30
AST levels in, 180
ECG and, 587
LDH and, 840
pleural fluid analysis and, 1048
Pulmonary perfusion scan, 877–881
Pulmonary rehabilitation exercises, pulse oximetry and, 1117
Pulmonary sequestration, angiography of, 89
Pulmonary status, plethysmography of, 1042
Pulmonary tuberculosis. *See* Tuberculosis.
Pulmonary valve anomalies, transesophageal echocardiography of, 583
Pulmonary vessels
angiography of, 88–93
CT of, 475
MRA of, 904
MRI of, 921
Pulse ox. *See* Pulse oximetry.
Pulse oximetry, 1117–119
methemoglobin and, 955
Pulse rate
calculation of, 587
monitoring of, 586
Punch biopsy, 249
Pupil dilation, 151, 656, 667, 815, 1150
Pure tone threshold, 1193
Purified protein derivative (PPD), of tuberculin, 1247. *See* Tuberculin skin tests.
Purine(s), in uric acid, 1323, 1324, 1326, 1334
Purine metabolic disorders, uric acid and, 1326
Purkinje fibers, 586
PVR. *See* Plethysmography.
Pyelography
intravenous, 817–821
retrograde, cystoscopy and, 548
Pyelonephritis
biopsy for, 226

BUN and, 1314
creatinine clearance and, 504
gallium scan for, 669
HP and, 723
IVP of, 818
renogram and, 1157
splenic CT of, 470
ultrasonography for, 1269
urine cytology and, 560
WBC casts in, 1334
Pyloric obstruction, gastrin stimulation test for, 679
Pyloric stenosis
capsule endoscopy for, 319
EGD and, 618
Pyocele, scrotal ultrasonography of, 1296
PYP cardiac scan, 966–969
Pyridoxal phosphate deficiency, ALT levels in, 17
Pyridoxine. *See* Vitamin B_6.
Pyridoxyl-5-phosphate. *See* Vitamin B_6.
Pyrophosphate cardiac scan, 966–969
Pyrosis, esophageal manometry for, 613
Pyruvate kinase (PK), 1119–1121
bilirubin and, 197
Pyruvate kinase deficiency, 1120
osmotic fragility and, 984

Q

Q wave, 587
QCT (quantitative computed tomography), 280–283
QRS complex, 587–588
Q-T interval
disopyramide toxicity and, 107
EGC and, 587
Quantitation, gastric emptying, 675–678
Quantitative computed tomography (QCT), 280–283
Queckenstedt's test, 41
Quinidine, 104–110

R

R wave, 587
RA (radiographic absorptiometry), 280–283
Rabies virus, viral culture and, 542
Radial artery puncture, 1408, 1411
Radial breast scar, ultrasonography of, 1267
Radiation
platelet count and, 1038
WBC count and, 1376, 1377, 1378
Radiation necrosis, PET and, 1056
Radiation seed placement, prostatic ultrasonography for, 1293
Radiation therapy
bone marrow biopsy and, 207
CEA and, 329
CT and, 422, 430, 452, 457, 461, 470
IFE and, 792
immunoglobulins and, 799
lymph node ultrasonography and, 1276
lymphangiography and, 893
MRI and, 912
RAST in, 34
uric acid and, 1323
Radiation-induced injury, liver-spleen scan of, 873
Radiculopathy, EMG and, 595
Radioactive gas, in lung ventilatory scan, 881, 882
Radioactive iodide uptake (RAIU), 1121–1124
Radioactive renogram. *See* Renogram.
Radioactive scans. *See* Scintigraphy; *specific scan.*
Radioactive seeding, cystoscopy for, 548
Radioallergosorbent test (RAST), 33–35
Radiofrequency ablation
liver, 1125–1129
ultrasonography with, 1125
Radiographic absorptiometry (RA), 280–283
Radiography. *See* X-ray.
Radiologic overexposure and protection
adrenal scans and, 7–8
blood pool imaging and, 278
bone scan and, 285
gallium scan and, 670
gastric emptying scan and, 676
GER scan and, 682
GI blood loss scan and, 686
Radionuclide(s). *See specific agent, e.g.,* Technetium-99m (Tc-99m).
Radionuclide imaging. *See* Scintigraphy.
Radionuclide liver scan, 872–877
Radionuclide perfusion lung scan, 877–881
Radionuclide ventriculogram, 276–280
Radiopharmaceutical(s). *See specific agent, e.g.,* Technetium-99m (Tc-99m).
RAIU. *See* Radioactive iodide uptake (RAIU).
Random urine collection, 1413
Rapid plasma reagin (RPR), 1203–1205
Rapid strep screen, 715–717
RAST (radioallergosorbent test), 33–35
Raynaud's disease
cold agglutinin titer and, 394
lupus anticoagulant antibodies and, 885
plethysmography and, 1042
Raynaud's phenomenon
plethysmography and, 1042, 1043
ultrasonography and, 1289, 1290

RBC. *See* Red blood cell (RBC) *entries.*
RDS. *See* Respiratory distress syndrome (RDS).
RDW (red blood cell distribution width), 1140. *See also* Red blood cell (RBC) indices.
Reactive hypoglycemia, in diabetes, 807
Real absorption, impaired, phosphorus and, 1026
Receptor-negative tumors, 624
Receptor-positive tumors, 624
Record keeping, OSHA standards for, 1448–1449
Rectal bleeding
  barium enema for, 189
  colonoscopy for, 399
Rectal cancer. *See* Colorectal cancer.
Rectal electromyography, 594–597
Rectal itching, proctosigmoidoscopy and, 1080
Rectal mucosa, proctosigmoidoscopy and, 1080
Rectal polyps, CT colonoscopy for, 443
Rectal prolapse, proctosigmoidoscopy and, 1080
Rectal tumor, ultrasonography of, 1293
Rectosigmoid disease, CT colonoscopy for, 443
Rectum, proctosigmoidoscopy of, 1080–1083
Red blood cell(s) (RBC)
  acetylcholinesterase in, 1108, 1132–1134
  bone marrow biopsy and, 207
  CSF analysis and, 342
  DAT and, 478, 479
  Hcr and, 727–728, 729
  hemoglobin content of, 1147
  hemosiderin and, 741
  Hgb and, 732–736
  HP and, 723
  IAT and, 481, 482
  in urine sediment, 1333
  inclusions in, 1145, 1147
  iron in, 824, 827
  LDH in, 839

  creatinine clearance and, 504
  deep. *See* Deep venous thrombosis (DVT).
  homocysteine and, 767
  MRI of, 908, 929
  plethysmography and, 1042
  renal biopsy for, 226
  splenic CT of, 470
  ultrasonography of, 1305–1306
Ventilation
  A/a gradient, A/a ratio and, 36
  pCO_2 and, 265, 266
Ventilation scan, 881–885
Ventilation-perfusion scan, 877–881
Ventilator(s), pulse oximetry and, 1117

Ventricle (cardiac)
function/dysfunction of
BNP and, 294
MRI of, 921
myocardial perfusion imaging of, 971
size, function, and motion of, blood pool imaging and, 277–278
Ventricle (cerebral), enlargement of, CT for, 434–435
Ventricular hypertrophy
echocardiography of, 579
exercise stress test and, 632
left. *See* Left ventricular hypertrophy.
transesophageal echocardiography of, 583
Ventricular irritability, potassium and, 1069
Ventricular septal defects. *See* Cardiac septal defects.
Ventriculitis, MRI of, 913
Ventriculogram, radionuclide, 276–280
VEPs (visual evoked potentials), 629–630
VER (visual evoked response), 627, 628
Vertebrae. *See also* Spinal *entries.*
RBC production in, 1135
Vertebroplasty, 1352–1356
Very-low-density lipoprotein cholesterol (VLDLC), 375
Very-low-density lipoprotein (VLDL), 869–872
Vesicoureteral reflux, voiding cystourethrography for, 552
VF tests. *See* Visual field tests.
Video swallow, 192–195
Viral culture, 541–544
Viral hepatitis. *See also* Hepatitis *entries.*
antimitochondrial antibodies and, 135
anti-smooth muscle antibodies and, 137
C3 complement and, 409
fecal fat and, 638
G6PD and, 698
LDH and, 840
TG and, 1237
VDRL testing and, 1204
Viral infections. *See also specific infection.*
amylase levels in, 63
β_2-M and, 961
bone marrow biopsy and, 208
C3 complement and, 409
fecal analysis in, 635
granular casts in, 1333
IgM and, 798
platelet count and, 1038
RF and, 1168
sputum cytology and, 556
total complement and, 411
WBC count and, 1376, 1377
Viral pericarditis, 1017
Virilizing adrenal tumors, DHEAS and, 569
Virilizing ovarian tumors, 1207
Virtual colonoscopy. *See* Computed tomography (CT), colonoscopy and.
Visceral larva migrans
eosinophil count in, 603
liver biopsy and, 229
Viscus rupture, KUB study of, 834
Vision
blurred, 1357
vitamin A and, 1370
Visual defects, 403
anticonvulsant toxicity and, 143
digoxin toxicity and, 107
fluorescein angiography of, 656
refraction and, 1150
VER and, 628
VF testing and, 1357
Visual evoked potentials (VEPs), 629–630
Visual evoked response (VER), 627, 628
Visual field, 1357
Visual field defect, VF testing and, 1357
Visual field tests, 1356–1359
Visual loss
detection and evaluation of, 1357
MRI and, 912, 937
Vital capacity (VC), 1112
Vitamin(s), deficiency of, amino acid screen in, 49
Vitamin A, 1369, 1370–1371, 1372–1373
prealbumin and, 1077–1078
zinc and, 1384
Vitamin A deficiency, 1370
Vitamin A intoxication, 1370
Vitamin B_1, 1369, 1370, 1371, 1373
Vitamin B_6, 1369, 1370, 1371, 1373
Vitamin B_6 deficiency, 766–767, 825, 1370
oxalate and, 994
Vitamin B_{12}, 1359–1361
bone marrow biopsy and, 207, 208
homocysteine and, 766–767
IF antibodies and, 822
RBCs and, 1135
Vitamin B_{12} deficiency, 1359
folate and, 659
glucose and, 694
homocysteine and, 767
platelet count and, 1038
RBC indices and, 1141
RBC morphology and, 1146
WBC count and, 1377
Vitamin C, 1369, 1370, 1371, 1373
hyperoxaluria and, 994
Vitamin C deficiency, ALP levels in, 30

Vitamin D, 1362–1364
calcitonin and, 302
phosphorus and, 1026
PTH and, 1004
Vitamin D deficiency. *See also* Rickets.
calcium and, 306, 310, 314
phosphorus and, 1026, 1029
Vitamin D intoxication, 1362
calcium and, 306, 310, 313
phosphorus and, 1029
Vitamin D_2, 1362
Vitamin D-deficiency rickets, amino acid screen in, 49
Vitamin D-resistant rickets, amino acid screen in, 49
Vitamin E, 1364–1366
supplemental, 1365
Vitamin E deficiency, RBCs and, 1135
Vitamin E intoxication, 1365
Vitamin K, 1367–1369
osteocalcin and, 986
Vitamin K deficiency
APTT and, 1011
AT-III and, 162
PT and, 1105
Vitamin K-dependent protein, 1095, 1097, 1104
Vitreous traction syndrome, VF testing and, 1357
VLDLC (very-low-density lipoprotein cholesterol), 375
VLDV (very-low-density lipoprotein), 869–872
VMA. *See* Vanillylmandelic acid (VMA).
Voiding, bladder pressure during, 545
Voiding cystography, 551–555
Voiding cystourethrography, 551–555
Voiding disorders, 545
Voluntary protection programs, OSHA-related, 1449, 1450
Voluntary ventilation, maximal, 1112
Volvulus
colonoscopy and, 399
proctosigmoidoscopy and, 1080
Vomiting
acetaminophen intoxication and, 66
antiarrhythmic toxicity and, 107
anticonvulsant toxicity and, 143
antidepressant toxicity and, 151
antipsychotic toxicity and, 159
blood gases and, 266
chloride and, 356
digoxin toxicity and, 107
EM and, 613
GER and, 681
GER scan and, 682
ketones and, 830
magnesium and, 898
MRI and, 912, 937
phosphorus and, 1026
potassium and, 1070, 1074
salicylate intoxication and, 67
serum sodium and, 1186
urine porphyrins and, 1052
Von Gierke disease (glycogen storage disease)
cholesterol and, 380
glucose and, 694
GTT and, 701
ketones and, 830
TG and, 1237
Von Willebrand factor, 1010
Von Willebrand's disease
APTT and, 1011
bleeding time and, 258
V/Q scan
perfusion, 877–881
ventilatory, 881–885
VZV. *See* Varicella-zoster virus (VZV).

W

Waldenström's macroglobulinemia
cholesterol and, 381
cryoglobulin and, 508
ESR in, 608
IFE and, 792
IgM and, 798
RF and, 1168
total protein and, 1093
urine protein and, 1100
WBC count and, 1377
Wall motion study, 276–280
Warkam syndrome, 384
Warts. *See* Condyloma.
Waste material, OSHA standards for, 1447
Wasting disease, creatinine clearance and, 504
Water intoxication, 356
osmolality and, 981
Waxy casts, in urine sediment, 1334
WBC. *See* White blood cell (WBC) *entries.*
WBCC. *See* White blood cell count (WBCC).
Weakness
anticonvulsant toxicity and, 143
antipsychotic toxicity and, 159
magnesium and, 898
Weber test, 1250, 1251
Wegener's granulomatosis, c-ANCA and, 115
Weight loss/reduction
Apo A and, 168
Apo B and, 171
barium enema and, 189

Weight loss/reduction *(Continued)*
glucose and, 693, 700
pancreatic CT and, 448
tuberculin skin test and, 1247
UGI series and, 1310
Werner's syndrome
Apo B and, 171
cholesterol and, 380
TG and, 1237
Western blot assay, for Lyme disease, 891
Wharton's jelly, DAT and, 479
Whipple's disease
5-HIAA and, 783
ALP levels in, 30
fecal fat and, 638
folate and, 660
GTT and, 701
White blood cell (WBC)
in urine sediment, 1333
LDH in, 839
White blood cell (WBC) casts, in urine sediment, 1334
White blood cell count (WBCC)
absolute, 1374
bone marrow biopsy and, 207
CBC and, 415, 419
cell differential and, 1373–379
CSF analysis and, 341, 342–343
pericardial fluid analysis and, 1017
peritoneal fluid analysis and, 1021–1022
pleural fluid analysis and, 1047, 1048
synovial fluid analysis and, 1199–1200
White blood cell (WBC) scan, 1380–1383
Whole-body bone scan, 284–287
Williams syndrome, 383
Wilson's disease, 313
amino acid screen in, 49
ceruloplasmin and, 346
copper and, 484
liver biopsy for, 230
uric acid and, 1324, 1326
zinc and, 1384
Wire malposition, chest x-ray of, 349
Wiskott-Aldrich syndrome
IgA and, 798
IgE and, 795
MPV and, 1037
platelet count and, 1038
Wolff-Parkinson-White syndrome, exercise stress test and, 632
Wolf-Hirschorn syndrome, 384
Wolfring glands, 1174, 1175
Work practice controls, 1442
World Health Organization, PT international normalized ratio and, 1104
Wound(s), bacterial culture of, 515–520
Wound healing, vitamin E and, 1365
Wrist
arthrogram of, 173–175
fluid aspiration from, 1199
venipuncture of, 1408
x-ray of, 1129–1131

X

Xanthoma, LDLC and, 376
Xenon gas, in lung ventilation scan, 881, 882
Xenon lung scan, 881–885
X-ray
bone, 1129–1131
chest, 348–351
esophageal, 192–195
KUB, 833–836
XYY syndrome, 385

Y

Yellow feces, analysis of, 635

Z

Zenker's diverticulum
barium swallow and, 193
ERCP and, 371
Zidovudine (AZT), 961
Zinc, 1383–1386
excessive intake of, 347
Zinc deficiency, 1384
vitamin A and, 1371
Zn. *See* Zinc.
Zollinger-Ellison syndrome
ALP levels in, 31
calcitonin and calcitonin stimulation tests for, 302
fecal fat and, 638
gastric acid stimulation test for, 672, 673
gastric emptying scan and, 676
gastrin stimulation test for, 679
PTH and, 1005
Z-score, bone mineral densitometry and, 281
